At HF and above, any reasonable thickness of sheet metal provides so much attenuation that invariably, much, much more signal gets around it and through small cracks, seams, and the like, that the attenuation of the metal itself can be considered perfect.

Hi Mike,

The quick answer is: you can't.

The working answer is: you approximate to a much coarser grain than
2x4 inch. Think of the grid, or the fence, in terms of wavelength and
try to make no two adjacent points in your mesh further apart than
1/10 or 1/20 wavelength.

If, after the application of that simple rule, you have excess
segments; then double up the mesh granularity near the feed point. As
fields are square and cube law creatures, proximity is a mighty
determinant.

Hi Jeff,

You got it. In fact, the unwary are far more likely to inject EMI
into a quiet system while trying to measure the coupling.

In real-world totally sealed systems, there are ways in and out that
do not violate shielding. These are medical grade instrumentation
amplifiers and signal conditioners. They employ either flux linkage
or photon linkage to pass signal and power between the host and the
sealed system.

In a flux linkage, the shielding can be laminate with a common point
of conduction. In photon linkage, only a pinhole is required through
the shield. The impedance of this has been well described by Roy's
coverage of below cutoff attenuators. The hyper-extension of this is
that the cutoff is so high, only light frequencies can pass
un-attenuated.

However, having introduced the notion of this fine pin-hole, I must
report there is an emerging concept of Optics that allows for small
holes to gather up disproportionate amounts of photons. Part of a
class of Optical diodes I believe.

An analogy:
you are 10 feet from a dense wall that has a BB sized hole in it;
you aim a shot gun at the hole and fire;
a third of the BBs go through the hole.

It would seem Maxwell's Demon has found a moonlighting position with
shuffling photons through pin-hole screens.

J. Harvey wrote:
"I saw a table that provided attenuation factors (dB) for various thicknesses of metals at various frequencies."

R-F current density decreases exponentially with depth below the surface of a conductor. There is less current to take a bite out of as as depth increases just as there is less current to take a bite out of at a distance along a lossy transmission line.

Skin depth depends on conductor resistivity. There isn`t much difference in the resistivities of copper and aluminum. Skin depth in a particular metal varies inversely with the square root of the frequency. At 100x the frequency, you get 1/10 the depth of penetration.

At 1 KHz, skin depth in copper is 0.0826 in.
At 10 KHz, it`s 0.0260 in.
At 100 KHz, it`s 0.00826 in.
At 1 MHz, it`s 0.00260 in.

The pattern is established so you can extend the table above if you would like.

The current has dropped at one skin depth to 36.8% of the magnitude on the surface. This fraction is 1/e. The base of the natural log is "e". This attenuation is 1 neper. Look up the number of db this is in your conversion tables, if you are interested.

At 10 MHz, you can see that skin depth in copper is 0.000826 in. This is less than one thousandth of an inch. How thick is your aluminum or copper foil?

Best regards, Richard Harrison, KB5WZI

You didn't say what frequency, but it shouldn't be a problem at HF or MF. First, make a series of connected horizontal wires 4 feet above the ground. Each wire should be about 1/10 wavelength long and one segment, for a total length of 100 feet. For example, at 30 MHz, this would require about 30 wires and 30 segments. Then, at each wire junction, drop a vertical wire that doesn't quite reach the ground. I'd terminate them at, say, an inch or two above the ground. One segment for each wire is probably enough for the HF band, even though the segment length would be a bit over 1/10 wavelength at the very top of the HF range. So you've now got another 31 wires and 31 segments, for a total of 61. The trick now is to simulate the ground connection. Four feet is too low to model using MININEC type ground, which you could connect directly to. You've got to use High Accuracy ground, which you can't reliably connect to. I'd begin by running a series of wires along the bottoms of the vertical wires -- that is, in parallel with the top of the fence. Another 30 wires and 30 segments, for a total of 91. Then I'd do a test run and look at the currents on the fence wires. At places along the bottom wires where you have quite a bit of current, you might want to run a few horizontal wires outward from the bottom of the fence to simulate a better connection to ground. Or you could do this routinely every 8 feet or so, since this is probably how often the actual fence posts penetrate the ground.

There's no need to use anywhere near 500 segments for this, for HF or MF at least. A more complex model than I've described will give virtually the same results.

Don`t be too discouraged at H-F. You can probably search on "screened room" and get some responses including radio attenuation provided by the screening under specified conditions. I copied a catalog design. It was a double screen, one copper insect screen on either side of the framing. This was about 50 years ago in an H-F transmitting plant with about a megawatt floating around. The screened room was nice and quiet. For our purposes the transmitters might as well not have been on the site.

There is another factor that comes into play called "transfer
impedance". This is the voltage drop
generated on one side of a shield or tube, because of the resistance
over the length of the tube,
caused by the current flowing on the other side. This effect
particularly comes into play when
coax cable shields carry large currents from lightning strikes. Part
of the current ends up on the
inside of the cable and thus on the center conductor as well.

A ham fortunately doesn`t need a full education on rectifying junctions to know that poor contacts can generate harmonics. This is the sort of "factoid" someone picks up from the "buzz". It is not covered in many texts so even an educated technician could be as ignorant as a less technically inclined operator. On the other hand, no prerequisites are needed to understand the simple fact that a diode can cause waveform distortion leading to the production of new frequencies. We have devices called diode mixers and diode detectors which are frequency changers. We could not reasonably expect a radio amateur to do a Fourier analysis and explain it on a license examination.

A problem caused by a rectifying junction is very rare and is not likely to be especially hazardous. Most problems may befall other hams as the bands are often harmonically related. We know that ham conversations are by law not of a serious nature except in an emergency when any type of radio could legally be substitiuted to serve the same function. The silly season has surely arrived in this discussion when such a way out proposition is raised.

Set scanner in location. Form coax as necessary to plug male N into female BNC. Yes, they fit. Same dimensions, just no retaining mechanism. Use your imagination to produce a retainer. One way is to take a BNC plug apart, chuck the retaining sleeve in a lathe, and put 5/8"x24 threads on the outside of it. Install it on the BNC, and then thread the N onto it. It'll drive the purists nuts!

A broad, expansive, experience is useful to
get the big picture of both the 'ideal world' (head-in-the-sand) issues,
and also the real world situations. The attitude that 'if I ignore it, then
it won't happen to me' will sometimes work, and sometimes the most
stupid people will win the lottery also. However, I am an EE also with
several other discipline engineering and development expertise. It is frightening
that knowing that I don't know everything (I am never satisfied with my
theoretical and practical know-how), that the community 'common knowledge' of
EE (both practical and theoretical) seems very weak, and somewhat disappointing
EVEN in the ham world. Ham radio had been a hobby of special technical
expertise, but it seems that the 'expertise' is becoming more and more
a happy surprise.

Blowing off the issue of using zipcord for feedline with only one of the first order
problems shows that the respondent isn't prepared to deal with problems
that are deeper or less obvious than using an almost totally incorrect
feedline technology. Jumping on one possibility of flaws with the test
example, seems to show a lack of complete understanding (not a complete
lack of understanding, but a lack of broad understanding.) I don't think
that I would enumerate 'power loss' alone, but consider perhaps 5-6
problems with zip-cord, where power loss is a rather coarse grained
description. Assuming the defect is actually hidden in something that
superficially looks right, 'power loss' isn't really going to point to the
cause/effect of the problem. For example, ignoring radation or coupling
into nearby metal pieces and junctions (which has been a significant
source of EM interference, but certainly not 100% of the time), there
are at least several obvious 'power loss' mechanisms due to the use
of improper feedline -- but the 'power loss' is a resulting effect, and not
the real cause of the problems. 'Power loss' is akin to saying that
"it don't work" -- the reason for failure is more important than "it is broke."

All too often, there are questions in the antenna and homebrew newsgroups
(with sometimes equally wierd or misguided answers) that show a
certain technical cluelessness in the community. Eventually, a reasonably
correct answer will often be provided, but the 'odd' or 'slightly wierd'

answers happen too darned often. Please refer to some of the previous
discussed SWR issues, for example.

>

> proposition is raised.
>
Again, you are the one who implied that the problem with
zipcord was energy loss. The context of my suggestion for technical
competence is with respect to high power operation. Actually, safety
could be an issue (of course), but more interesting issues appear
because of coupling into other materials and surroundings. Loss
because of dielectric, I2R, etc are pretty straightforward impairments
caused by zipcord. My zipcord example was given for an obvious
problem, but what happens if everything superficially looks okay?
It is okay to ask for help, but that kind of defeats the notion that
there is a responsible operator and maintainer of the equipment.
At least, you didn't complain about SWR!!!

It is fallacious to assume that just because you haven't heard about
a SPECIFIC problem occuring, that the issues aren't important. There
are MANY MANY issues that happen all of the time, but being able to
diagnose non-obvious problems helps the operator and maintainer
fulfill their responsibility. SOMETIMES, you even have to hunt around
your system (no matter the technology) to sniff out problems. This
applies to almost any kind of technological device, where part of
responsible operation (esp at high power) would include searching for
potential problems. You can't find all of them, but an SWR meter
isn't going to be sufficient (and it doesn't really measure what many
people think anyway!!!) :-).

It is exactly the head-in-the-sand attitudes that really beg for technical
standards. It has been too long that people have been spoiled by purchasing
their hobby for money, rather than really learning and understanding
their tools. Maybe it is time to rent a certified ham radio operator, so that
those who aren't competent to follow the rules and regulations WRT
technical standards will be able to comply. :-).

John

I should probably do a lot more snipping than I did but just what is the gripe with using zip-cord or any other twin lead?. I'll buy the dielectric complaint at a high enough frequency but the rest of the issues don't seem to hold water.
A balanced line by its nature doesn't radiate into 'nearby metal pieces' (within limits of course), nor is it somehow inherently more leaky than coax. The OTers religiously used dual RF ammeters in both wires and would trim accordingly...maybe this isn't the case with the appliance guy who would shove twinlead into the back of his JA-2002 model rig.

I don't read too well off of a monitor at 2 AM but the gist seems to be that you have to be of a certain technical prowess to understand balanced antennas/transmission lines when that is actually one of the more basic concepts that one may encounter when playing with antennas.
To veer back onto the topic of the "7 steps", this might be one of the areas that needs a tad bit more illumination for the dis-illuminatedati.

Trickery in the numbers.... I can make those numbers "say" one thing, as you can have them "say" another.... Accountants do that on a daily basis.... Overall, there are not enough new hams coming into the ranks that will be needed to replace/fill-in the spots that will invariable happen due to death of the larger percentage of current hams, that being the 45-75 age group. Within 10-20 years, we will lose a good chunk of that age group either to accidental or typical health related issues.

Whether or not someone wants to argue the incentive licensing issue, or not, the whole thing won't do a darned bit of good, unless there is the public's knowledge about ham radio.

Hello..,

You may install 4nec2(x) where you like. The suggested C:\4nec2 in the _ReadMeFirst.txt file is only used as an example.

The directory specifications in the 4nec2.ini file are set when you select your directory where your *.nec files are located. The other directories can ba manually changed by using the 'Settings -> Folders' option on thye 'Main' form.

Read the -ReadMeFirst.txt and the Help file when you want to interface with the VOACAP/ ICEPAC propagation prediction freeware.

Concerning the 4nec2XS engine the following: Initially I used the 'standard' nec2d***.exe, once created by Jos Bergevoet. However, when XP was introduced this DOS based executable would not run any more. So a new engine (nec2dX) was created by Raymond Anderson to overcome this problem. In turn I used this exe to integrate the nec2d and the SomNec routines into a single nec2dXS.exe.

See the ReadMeFirst.txt file for more background info about the pro's and contra's for the nec2dXS engine.

Arie.

Hi,

I've just put the paperwork in the post to get my HF callsign - and the only thing holding me back is the lack of an antenna system.

I've measured the length of my garden and can achive a maximum of 130 feet straight-line run. There seems to be lots of options around for a multiband solution - G5RV, Zepp, straight-dipole, Windom,etc. and I'm somewhat confused as to the best solution (bearing in mind I want to homebrew the antenna).

I already have a 1/2 size G5RV but do not intend to put this up as the balanced feeder is in poor condition - however the insulators,etc. are fine and I will recycle these.

Looking through previous posts, lots of people suggest constructing a half wave dipole of the longest length possible. And the feeding that with balanced feeder back to the ATU? Assuming this is the way forward - Can I ask:-

a) What impedence should the balanced feeder be? I seem there is 450 and 600 ohm versions?

b) Does the length of balanced feeder matter?

c) Where the feeder meets the dipole - Do I need any form of matching?

d) If I wish to bring coax into the house - Do I need a balun to tie into the balanced feeder?

e) I have have quite alot of computer gear which is always powered up. Given this, is it better to reduce the lenght of balanced feeder + increase the coax length to reduce local interference pickup.

f) I have a long length of multi-stranded PVC coated wire. Is it OK to use this for the antenna? I appreciate its tensile strenth isn't ideal but I want to use the materials I already have to hand.

Sorry if these are rather obvious questions which have been asked before - I did check through the archives before making this post.

Thanks for any advice offered,

73s Steve.

John Dyson wrote:
"A broad, expansive experience is useful to get the big picture of both the "ideal world" (head-in-the-sand) issues, and also the real world situations."

Tongue-in-cheek issues initiated this thread which quickly turned to serious differences over reform of the amateur radio hobby and licensing requirements. Licensing is a minimum entrance for initiaion of amateur transmissions, not a diploma certifying expertise.

The people own the radio spectrum in our democratic republic. This spectrum is regulated to ensure maximum utility and enjoyment as a goal.

Licensing is a regulation tool to simplify enforcement of necessary rules. If you don`t have a proper license, no argument is necessary to show that you are in violation when using the spectrum without the specified credential.

Licensing is simply a minimum requirement to access spectrum for radio amateurs. Expertise may be a requirement for legal bar exams, medical licenses, certification as a public accountant, or as a professional engineer, but we are discussing AMATEUR RADIO, not a profession. Get a grip!

[snipped]

> You have to be careful in that not all characteristics are fungible
> between RF and digital. For one, a digital signal is 1's and 0's and

I disagree. A cable is a cable regardless of what type of signal is
used. Now if you want to talk about phase dispersion or loss per
frequency, which you mention below, that is a different story. Of
course I am not talking about cables that have some type of dielectric
that has a molecular absorption line at the frequency you are trying
to use. PVC insulated telephone cable does not like RF at more than a
few watts. Been there done that.

Also, don't forget that for a 100 MHz 'digital' waveform you will need
500 MHz or more bandwidth to faithfully reproduce the squarewaves.
That is why you rarely see actual 'square waves', even on digital
signals.

> as long as there is sufficient S+N/N ratio (roughly 12dB or better), a
> lossy cable is not that much a problem. The problem for digital (and
> not necessarily RF, or at least not at this scale) is dispersion
> (phase integrity). That is the number one killer. Even then, some

This is called group delay. It is the slope of phase vs frequency.
This is a major concern in RF. Communication Satellite makers are
very concerned about this, even over the relatively narrow bandwidth
of 100 MHz (on a 29 GHz carrier)

My main point is that 'digital' is just a subset of reality. We get
so used to working with just a few small 'pieces of the puzzle' that
we forget that there actually is a 'big picture'.

Agreed, but as Bill implied, balance is everything. Twin-lead is installed on standoffs which coax doesn`t need to keep its balance.

If you are located off the centerline of a balanced pair, energy reaching you from the twin-lead likely doesn`t quite cancel.

Zipcord should excel in balance as its conductors are very close together. Otherwise, it is just low-impedance twin-lead, with a lossy dielectric in some cases.

Richard I thought there was more to it than that.
I seem to remember that the fact that whether
the material is in tube form, solid or thin plate
requires a correction factor. In other words, the
skin depth is not an exact science.

Hi

I guess that the idea of the design is to dig the ground post into the soil (or concrete) so that the 80m coil is just above earth.
What is the best way to mount the ground post of the HF6V, when mounting direct on the ground surface ?
I think some use a pipe with an inner diameter coresponding to the OD of the ground post, but how to prevent rain and moist to accumulate in the pipe?
Here in rainy Scandinavia I am afraid that water will start a galvanic corrosion, because the iron pipe and aluminum are electrically different.

Or does any mount the HF6V on a little post, so that the ground post is just above the surface ?

Mogens

Does this mean 7 MHz, 5-watt QRP is OK on network-quality twisted
pair? What is the impedance?

There is no point in doing this unless it has lower attenuation than
RG-174. Does it?

Here are some specs (dB/100ft) on Cat 5e cable from
http://www.clear-bit.com/ClearBit/5edata.htm

MHz
FREQ TIA SPEC WORST CASE AVERAGE
1 2.4 2.0 1.9
4 4.5 4.1 4.0
8 6.3 5.7 5.6
10 7.0 6.5 6.4
16 8.8 8.1 8.0
20 10.3 9.2 9.0
25 11.4 10.3 10.1
31.25 12.7 11.5 11.3
62.5 18.5 16.6 16.3
100 24.0 21.4 21.0
200 - 31.3 30.7
250 - 35.6 34.8

Impedance is around 100 ohms.

Wes somewhere you stated that you were having a heck of a time
modelling this style of feed.
I just had cause to model this in connection with something else
and I also could NOT model it where it reflected my claim.
This ofcourse is embarrasing to me as it will invite
some jeering but the truth must be said.
I would add that this and many other experiments were done
before the advent of modeling and later when I did use them
on other things I made many learning errors as many others did.
When I made the claim it was because of numorous experiments
that provided broad banding and I mean numorous.
In defence I can only suspect that the thin insulation
or the small gap coupled with very close thin elements are the
culprits
I am not sure that I claimed to have modelled it as it must be close
to ten years ago when I did that work and memories do not always work
well.
What I am confident in is that the events took place and worked as
claimed.
Sorry for any inconvenience I may have caused you.
(The multi frequency antenna DOES model as claimed)
Let the derision begin.....

N4LQ wrote:
"Twisted pair feeder is described in my 1937 ARRL Antenna Handbook. Impedance is about 75 ohms, affected by noisture and has more loss than coax. It became standard for telephones and door bells."

Why not use 75-ohm coax in place of twisted pair? I remember the phone twisted pair stapled to the wall. That isn`t an impedance match for phonelines, ringer, or telephone set, but at audio frequencies the premise wiring is short in terms of wavelength. Phone drop wire and military field phone wires were often twisted pair too.

Twisted pair was used for r-f in 1937. That was the year we replaced our Majestic TRF console with a new 17-tube radio that included (4) 6L6`s driving a 15-inch loudspeaker. It wasn`t even from Midwest. It was a GE. Dial illumination shifted from red to green as you tuned in stations (saturable reactors controlled by the AVC).

Twisted pair was used with the "Vee-Doublet" antenna kit that came with the "all-wave" radio. The balanced antenna was transformer coupled to the twisted feedline to the radio. It worked well as a low-noise antenna system.

Source record: 130605

The advantage of the half-sloper (over a vertical with gamma matches) would seem to be that the high-current point is elevated and will, we assume, radiate better. Like most towers, mine is somewhat obstructed at ground level. I would guess that the high feed point is the primary attribute of a half-sloper.

Insulating the base of a TX-455 would be a mechanical challenge that I will skip.

Thus far, my question about feeding it at the top or at the top of the second tower section has drawn a few suggestions to feed at the top (and ignore any disturbance to the quad's pattern).

Okay, now you are starting to see my position!!! I am not meaning to be
contrary, but I haven't really been suggesting the universal need for a
technology competency exam in Ham radio. I have been suggesting a
need for good EM citizen competency for high power transmitters.

However, the day-to-day NEED for competency in Morse code is rather
limited nowadays, yet is still required in some cases, apparently only
because of treaty reasons and attitudes that might try to maintain an elitism or
exclusive club.

So, my argument, all along, is that normal day-to-day usage of any
high power transmitter (even purchased) does need special know-how
in order to resolve problems (safely and EM citizen responsibly) that
aren't as common with lower power
operations. Sure, there are some ad-hoc help forums that can help
non-savvy people mitigate problems, but it is apparent to me that
problems can too-often exist without knowing, mostly because of
the lack of a squeaky wheel.

The relative importance for RESPONSIBLE HRO behavior is that technical
competency (unless there are Ham radio installers and equipment
certification authorities) is much more important than anachronistic Morse
code skills.

In fact, I am NOT REALLY advocating an incredibly difficult qualification
exam. I am advocating the fact that time/effort for newbies is best spent
on learning the technology (not necessarily to the engineering level) in
enough detail to avoid being a bad EM citizen (and personal safety) rather
than an old-time skill that isn't really needed for most reasonably
plausible cases of communications or the public service aspect of Ham
operations. A slightly off-topic, but perfect example of the safety issue is
that even professional remote broadcast crews have been hurt by disagreements
between antennas and powerlines :-(.

Honestly, I do tend to be a 'cart before the horse' person, where I tend
to become technically an expert before jumping in and doing something
as a hobby (and hopefully at work.) This sometimes initially side-tracks

the hobby aspect, and I have destroyed more than one hobby in becoming an expert in the field, getting a job in the field, and losing much of the enjoyment aspect of the hobby. Frankly, I am currently in a "detox" phase of such a situation, where my FreeBSD hobby (where I did some seriously good stuff) turned into a job. :-(. Few who worked with me on the project knew that I was really an EE who happened to do computer stuff (when needed in the hobby or at work.) Even when doing OS stuff at AT&T, it wasn't uncommon for the RF guys to ask me for help about some tricky problems (e.g. unforseen sources of parametric nonlinearities.)

Maybe I do take things too seriously, and that kind of criticism is accepted by me, and probably accurate!!!

John

We have a generation of kids that are used to the overwhelming sensory
experiences of video games, and even the WWW. In order to gain more
participants, it seems to me that the issue of 'attractiveness' is more
fundamental than the licensing qualifications.

In a way, it makes little sense to decrease the qualifications if they are
already so low, and even that slight impediment is stopping participation.

People today have so many opportunities for day-to-day communications,
that there is even a bit of a movement to hide from the on-demand
communications distractions. Ham radio already has alot of competition
from other communications systems. I am not claiming that current
communications systems are equivalent to Ham Radio, but because there
is a little bit of a 'dream' that is satisfied by Cellular or the WWW (for
example) that makes the results of Ham Radio superficially less exotic
and appear to be less of a challenge. (Of course, that isn't quite true,
but appearances are sometimes more important than reality.)

Ham radio will tend to draw more interest when it can provide a compelling
and glitzy 'features.' This is a difficult thing to decide, because some of the
'best' glitzy things to do might take LOTS of bandwidth and/or might not even be
applicable to ham radio.

I suspect that there are the 'ham radio' club marketing (e.g. ARRL) are
trying to figure out some killer applications for the hobby. Of course, it is
a different kind of killer application than 'Spreadsheet', 'Video games' or
somesuch, but I suspect that there is something out there.

Ham radio already has SOME applications (contests, emergency communications,
casual communications, electronics hobby), but additional *generationally relevent*
applications need to be found.

From what I see on the outside, Ham Radio isn't dying, but given the powerful
tools available, it seems odd that more appropriate high visibility hobby
applications havent been found (or publicized much.)

Hi Bill,

The simple response is to build the gamma match at the top instead of
the bottom. If the match is adjustable enough to cope with this novel
site, that should be enough.

Hi Ken,

Your last comment is the most telling. One of the most oblivious
offerings I've heard is that QRP, being a lower wattage service,
needn't worry about sub-par components because the power lost is
trivial.

If QRP needs ANYTHING, it is premium components and maximal
efficiency.

No, it is a very exact science!

Some textbooks derive the classic skin depth formula for one specific cross-sectional shape of conductor, but that's misleading. If you zoom in to look at a microscopic patch of the surface, it can be proved that the skin effect is generated "locally". It doesn't depend on the larger-scale shape of the conductor, and it doesn't depend on the reason why the RF current is flowing

A copy of the proof (not by me) is at:
www.ifwtech.co.uk/g3sek/misc/skin.htm It's heavy EM math, but the conclusion is clear and simple:

If RF current is flowing across any conducting surface, the skin effect will always happen. That means the skin depth is independent of the size and shape of the conductor (unless dimensions are so small that they are similar to the skin depth itself).

Because skin effect is generated locally, independent of the RF circuit configuration, it can be taken as a "given" when you're trying to work out how the circuit operates.

Peculiarly enough, the 'big picture' is more simple than its subsets.

The electrical story of transmission lines, from DC unpwards, is contained
in 4 simple, so-called primary constants - R, L ,C and G.

Makes one wonder what all the fuss is about. ;o)

Hi Jim,

Digital is a subset of anything? Digital requires a superset of characteristics compared to standard analog RF. You added to the list yourself.

As I pointed out, and as you have confirmed through expanded examples, Digital characteristics and RF Power characteristics are not fungible.

Hi Richard,

My buddy has an old power line engineer's handbook from the turn of
the last century. In it (and easily confirmed by observation as you
drive down the road) is the portrayal of how to twist the power lines.

Twisting lines is the single greatest way to reduce interference by
reducing the area of a loop, and then creating in-series opposing
loops to cancel long wavelength induced components. It can knock down
this kind of interference by 60dB.

Art, KB9MZ wrote:
"Richard I thought there was more to it than that. I seem to remember that the fact that whether the material is tube form, solid or thick plate requires a correction factor."

That seems reasonable as a significant factor in skin depth is distribution of magnetic lines and their inductive effect.

However, from Terman`s 1955 tome, page 23:

Current at depth z / current at the surface =
e to the minus depth / skin depth

Skin depth is: 5033 times the square root of the resistivity divided by the permeability x frequency. The answer is in centimeters.

For copper this reduces to 6.62 / sq. rt. frequency. I believe this is at 20 centigrade degrees. My little table was computed from this formula. Terman says: "At 1 Mc the skin depth in copper is thus 0.0066 cm, or 0.0026 in."

I don`t find a form qualification in Terman`s exposition. Thus, I conclude it is inconsequential. My skin depth calculation agrees with Terman`s, so I don`t believe I made a mistake in my table.

Best regards, Richard Harrison, KB5WZI

Well here is how mine works.

#12 Stranded pvc coated house wire, is stretched 100 feet between two trees, using a spring and pulley to maintain about 20 pounds tension as the trees sway.

Home made Parallel Line (1 inch spacers, impedance unknown) from doublet to first wall of house. Drilled two 1/8 inch holes same spacing as feed line and pushed conductors through, spliced on inside.

another 30 feet then a 1" plus hole drilled in wall, and feed line fed through hole. Filled in with plastic bag to keep draft and animals out.

Connected to (balanced) tuner.

Good Luck.

AFAIR, the skin effect results from the AC field in/around the material.
By referencing some EM books, and a little bit of calculus, the skin
effect should be relatively easily predicted. It is likely a near EXACT
science, but the plug'n'chug formulas aren't likely always applicable.
(I seem to remember, deep in the recesses of my memory, that
skin effect is easily predictable -- but my memory also glitches
at times on subjects like this that I don't deal with every day.)

If someone is really, really interested, I might be able to find the
theory and basic equations, and show some examples. However,
even the techno-stikler me isn't really that interested :-).

Much stuff like this (including antennas and stripline stuff) can be
done with finite element approximations on the computer. Alot of
the stuff resolves from diffeqs and/or line/surface/volume integrals.
None of it is brain surgery, but the terminology in literature can
sometimes boggle the mind. Simple, regular shapes can often
be solved into explicit formulas. It might even be true in the
practical case that the skin effect isn't extremely sensitive to shape,
but it seems that significant changes would affect the behavior
of the flow of AC.

When embarking on new interests (in details), the hardest part
for me is to find the tutorial and detailed reference material. The
2nd hardest part (but often taking the most time) is learning (relearning)
the terminology. The actual 'facts' learned in the process are
usually extremely understandable, but the terminology short-cuts
and traditions can be stumbling blocks. (e.g. a good degenerate
case is the EE use of 'j' for the imaginary axis, while math
people tend to use 'i'. The bad news is that i and j haven't
historically always been formally the same thing, even though they
seem to be used interchangeably!!!)

John

3232. Re: Simple horizontal antenna advice

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-25 18:20:18 UTC

Source record: 130621

Steve,
First, understand that an 'all band' antenna is always a
compromise. It almost never works as well as you'd like on
some band(s). Keeping that in mind, then;

a) Forgetting cost and availability, the higher the impedance
the 'better' balanced feed line. Since 450 ohm is more
common, it's what you see used most often, and it will
work just fine.

b) Yes and no. There will be times when the tuner just can't
make a good enough match to work well. The length of the
feed line can be changed a bit, and in most cases the tuner
can then make a good enough match. It takes a bit of
'juggling'
but a length can be found that is usable for all bands.

c) No.

d) If you want to use coax to get into the house, then use a balun
outside, and the shortest run of very low loss coax possible.

e) Not really. The coax run should be as short as possible. You
would get the same amount of interference from coax as you
would
from a balanced feed line.

f) The wire used for the antenna should be strong enough to hold
up
it's own weight and the feed line (if it isn't supported). You
will have a better idea about your wire's strength than I
would.

The only reason to use a balanced feed line rather than coax is
the lower amount of loss of the balanced line, or it's ability to
stand a higher SWR than coax before 'biting the dust'. There will
almost always be some loss, though.
Another alternative is to use multiple dipoles from a common
feed
point, and a coax feed line. That makes routing the feed line
easier
than balanced feed line, and you usually don't have to worry about
it's
length. One of the draw backs to doing that is that the supports
for
the antenna(s) have to be stronger because of the added weight

(not a
whole lot, but still at least some stronger).
Good luck...
'Doc

Hi Anad,

The point of a newsgroup is that there are more than just you and me following this line of inquiry. We function as surrogates for a wide community, thus the need to spend time on covering what to you may be old ground.

It is interesting that you find a balanced feed interesting. Why? You now need to describe what you mean by the rather jarring notion of a slot and a loop in the same context. THIS is where we get into the nut of the matter, and the point that keeps everyone reading.

You still need to provide a picture (not posted here, but to an URL). This is an expectation not of us, the older generation, but a lifestyle choice vigorously embraced by the students of today (you are with it, aren't you?). Sending me a picture does nothing for the rest of the readership (you are not the only student who attends this group). If you cannot find a way to publish this on the net, then go ahead and send it to me and I will do it.

I have worked for many, many companies. I am a consultant to Venture Capitalists and do research into technical and scientific feasibility of new products, ideas and so on. I have made presentations to at least $100 million in funds managers seeking projects. The fields I have performed R&D (actual construction, not just imaginings) in include Avionics, Medical Applications, Pure Research, Wood and Paper, Superconductivity, Telecommunications, Power grid, Instrumentation, WWW, Electronic and Physical Standards, Nanotechnology, RF communications, Environmental risk assessment, Nuclear contamination control, and on and on. All with only a degree in English (if you read this board more, you would find those who've done less and hold advanced degrees find my Shakespeare tedious). I've also spent a

number of years teaching electronics (component level) and RF communications systems to advanced Technicians and Engineers. As that was in the Navy, my students had to put up with my Shakespeare (Rank Hath Its Privilege), but then I had a higher calibre of student who could respond in kind rather than gripe like a malingerer.

Hi Richard,

Unless it supports a caprice:
>>the events took place and worked as claimed.
When asked for proof:
>>I am not sure
...
>>memories do not always work well
memory seems to be a malleable quality favoring confusion and/or
advanced topics in fraktal Physiks.

Yes. 100 years ago, predates most powerline protective relaying and carrier systems. Today, much of the burden has shifted to microwave.

100 years ago, powerline transpositions were probably demanded by the phone company to reduce induction into their lines. Of course, you have seen the special insulator assemblies the phone company uses for transposition of its own open-wire lines.

In Tierra del Fuego, the phone line across the island was just a single low galvanized steel wire with an earth return. This was about 50 miles long. But, there was no electrical power system line to interfere with it.

Under "Outside Plant Noise Causes", the phone installer`s handbook says:
"The basic source is generally high electric power system influence in combination with poor or marginal plant balance."

Twisting 300-ohm twin-lead has also been used to clear up the picture.

Best regards, Richard Harrison, KB5WZI

3239. Re: Reg vs Smith

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-25 21:08:26 UTC
From: k7itm@aol.com
Message-ID: <3200347.0211251308.3abb8492@posting.google.com>
Source record: 130628

Hi Reg,

We should say, I suppose, that I use Smith charts to display results, because they help me visualize what is happening. I can see a lot at a glance. In general, I don't use the chart as a calculating tool, like a slide rule. Instead, I use processor-based calculating tools to do the calculations. One of those happens to be tied up with a typical Smith chart display, but the calculation it does includes, for example, line loss. Although it displays its results on a Smith chart (which I happen to appreciate), the results are also available in tabular form to way more digits of precision than I'd ever be able to use.

Alas, that program does not do everything that I might like. However, it's never been difficult for me to use other tools to handle those cases. The other tools include a programmable calculator, Excel, Scilab and Mathcad, all of which easily handle complex math, and even Excel, which also handles complex math, albeit clumsily.

The assumption of Zo real tends to work OK for what I do, but again, use of the proper program will handle all that nicely for me when I do need to consider complex (and frequency-dependent) Zo. It's certainly possible to normalize the Smith chart to a non-real impedance, though I belive that changes the shape of the lines we normally consider "constant reactance" and "constant resistance". (After all, if you multiply a resistance by a complex number, it becomes reactive... For example, with real Zo, if you add a pure resistance, the reflection coefficient stays real and you just move along the x-axis of a Smith chart. But if you add a resistance to a complex Zo, the reflection coefficient is complex, and that's represented by a point off the Smith chart x-axis.)

So in summary, I agree strongly with letting my computing tools handle the drudgery, I just like graphical displays of the results that help me see the big picture. _Sometimes_, even often, the Smith chart is the right visualization tool for me, but sometimes it isn't (and I appreciate that it may NEVER be for some people, too). However, the graphing capabilities of the various programs make it reasonably easy for me to display the results in a way that helps me out when Smith isn't the right answer.

I'll defer to others' inputs on the stub electrical length question.

Cheers,
Tom

Secret handshake....I had a good laugh over that one. Good
grief...Nothing has ever been secret about morse code. And the funny
part is we hams had nothing to do with implementing a code test. Also,
the license exams are not "know everything or else" types of tests.
They are just meager entrance exams. The usual ham learns much more
AFTER he gets a ticket, not before. Also, it takes many years to learn
all that can be learned about radio, or whatever else related to the
hobby. If thats even possible. I've been farting with this crap for 31
years, and I've still got a long way to go in order to even think I
might know all I need to know. The reality is most will never catch
up. Same with computers, and coding. I've done quite a bit of software
work in regard to flight sims over the years. If I drop out and rest
just for a few months, I fall so far behind the "envelope" that it's
hard to catch up again. The technology progresses that fast. It
progresses almost weekly. When I took my ham test, code was a non
issue. It was part of the test, and you learned it if you wanted a
ticket. Pretty simple really. If they drop the code test totally in
the future, fine. But until then, a 5 wpm test is required, and
whining about it here is not going to make it go away. Sheesh...It
wasn't long ago that 13 and 20 wpm were required. The code whiners
should count their blessings...To me, 5 wpm is no-code for all
practical purposes. It's too slow to be of much use on the air. :/

Yep it has, Mark. W5DXP and W5FQC were the only individuals in
Madisonville High School in the early 50's who knew Morse Code.
We used it quite often to send secret messages that our teachers
couldn't understand and hardly noticed. It was particularly useful
during exams and double dates.

==========
Bill, please forgive the intrusion, but the idea that the high current
portion of an antenna wire does most of the radiating is a popular
misconception propagated by Old Wives and technical editors. It is equally
illogical that most of the radiation occurs from the ends of an antenna wire
because that is where the highest voltages occur.

Whichever "Alice in Wonderland" argument is believed can lead the believer
up the proverbial garden path when it comes to antenna design. Marconi, a
contemporary of Lewsis Carroll, knew better.

Source record: 130634

You might want to consider using a different tool for this. 4nec2 includes "BUILD", which can apparently generate the "gridded surface" you are after, then can handle the additional segment load required to evaluate it. I haven't used it for this particular shape, but BUILD's "patch" generating feature looks like it will do the job. 4nec2 is free.

Another tool that could probably handle the segment load is MultiINEC with generic NEC as the engine (needs EXCEL, 97 or better, but is also free), and MultiNEC will accept the NEC output from BUILD as well.

What conductivity will you use for galvanized fence wire? I couldn't find any info on conductivity a while back when I was looking.

Steve,

If it were me, I'd run a "dipole" as long and as high as possible and feed it directly with open wire feedline. Use a link coupled antenna tuner or double balanced design; a tuner with a balun is an option but not as preferable as the first two. Impedance of the feedline is unimportant here. For multiband operation, the impedance will vary widely from band to band so it will be fine some places and not others regardless of what impedance you select. High SWR will have little loss in this instance. Length of the feedline can be considered non-critical although a limited range ATU might be unhappy on some bands necessitating the addition of some added feedline. I don't have a computer, I use a Macintosh instead, and there is no noise pickup and the Mac is just 2 feet away from the feedline.

Best of luck. If you'd like to discuss it further, just send me your non-spam email address.

73s,

Evan

Yes, I did that when I used this antenna at my last house. I drove an
aluminium pipe (can not recall the lenght) into the ground and
strapped the bottom of the BUTTERNUT on to that. They were a "special"
strap that a friend in industry gave to me. They held the antenna very
well. I also guyed this antenna with light, green garden twine that I
got from a garden centre. That kept it upright and there was no sign
of it bending over a period of eight years.

Mounting it in this fashion allowed me to unstrap it and I had the
complete antenna when I moved house. In just hammered the redundant
ground pipe further into the soil until it disappeard !

Hi again,

Thanks for everyones replies - Good to see a united concensus.

I did a bit more trawling on the net and found this useful article:-
http://www.hamoperator.com/antenna_shootout.html (with reference to
flatop antenna).

I intend to follow the instructions for this (although I will initially
start with open feeder all the way to the ATU). This design (and
everyone elses) seem v.similar to the G5RV - What is it about the G5RV
which makes it different?

Thanks for everyones comments so far - I'll report back with my findings
once I get it constructed (and I've received the new callsign!),

Hi Malcom,

The plan was for Steve to submit an antenna and the challenger was to "improve" it with genetic software. Both the original and then the modified one were to compared on the basis of the FOM agreed upon before the modification was performed. What I posted was Steve's criteria for the FOM. That specification was offered to him as the challengee to define.

The problem here is that this challenger is a business. That business is not going to reveal anything but the "results"; you are not going to see that product file (owned as an IP by and for the company). This has been a consistent behavior by this business for a number of years. In fact this challenge is in response to a similar fated challenge this time two years ago. Steve submitted 6 antenna designs for our consideration that thoroughly trounced the "fractal champion" on both their native merits, and even more so on the champion's terms of FOM (something like 10:1).

Not one byte of model file nor wire list has been offered by the failed champion against Steve's 6 successful challengers since that time, and yet this company maintains Steve lost and that some other guy (curiously an employee of the company) won instead. No model was offered for our review then either.

So, that gives you more than you cared to know, and may have not answered your question. In that regard, I hesitate to suggest you seek an answer from the source. Instead, the archive is more sure, but equally bloated with editorialization such as mine. If you do a search, be sure to use the boolean NOT SUE, so that you skip over that business' legal threats to the Ham membership.

3256. FS: Diamond SRH-519 & SRH-805 HT Antennas SMA Mount. 144/440 Dual Band

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-25 23:41:25 UTC
From: frank@damato.com
Message-ID: <1276490d.0211251541.fffde94@posting.google.com>
Source record: 130644
Cross-posted to: rec.radio.swap,rec.radio.amateur.equipment,rec.radio.amateur.antenna

Selling each antenna for $20 (includes shipping price). Antenna's are brand new, still in original yellow plastic cases. I have no need for them. Received them in a swap. you can see a picture of them at www.frankdamato.com/diamond.jpg

I Accept Paypal as Payment

The Diamond SRH-519 is an HT antenna for 2 meters and 440 MHz. It is 8.5 inches (21 cm) tall. This flexible antenna is black. Gain is a 3 dBi and it can handle up to 10 watts. This antenna terminates to a 50 ohm SMA. It is also very effective as a receive antenna for these bands: 150, 300, 450 and 800 MHz.

SRH-805 Diamond 2m/70cm SMA Low Profile Helical * Tx: 144, 430 & 1200MHz * Rx: 150/300/450/800/900MHz * 10W Max power handling * 1.75 inches (4.5cm long) * SMA fitting
Extremely low profile, yet provides transmit (Tx) capability on three bands and offers useful wideband reception, also for use with scanners. Suitable for Horas, Standards and Yaesu.

E-mail me with questions at frank@damato.com

Evan, do you ever feel guilty about recommending a random length dipole in conjunction with a random length open-wire feedline with any big Zo, plus a good tuner?

Don't you think it deprives newcomers of all the happy days, months, years which you probably experienced messing about, experimenting, with the other inumerable and less efficient cominations of wires, lines, loading coils, radials, baluns and tuners?

There's no difference except that on most bands it is 1 or 2 dB less efficient than its multiband competitors. It's that length of coax which does it. Dump the coax and it will behave normally. But you will no longer have a G5RV.

You'll find that worrying about the conductivity of the fence wire
(which will be that of zinc, assuming the coating is reasonably thick)
is a waste of time. With as much surface area as the fence has, the loss
will be negligible.

Hi Tom,

Well, if the truth be told, I'm not nearly as fond of Lear as I am of
Sir Walter Raleigh, particularly "The Lie":

,,,
"Tell physic of her boldness;
Tell skill it is pretension;
Tell charity of coldness;
Tell law it is contention.
And as they do reply,
So give them still the lie.
...
"Tell arts they have no soundness,
But vary by esteeming;
Tell schools the want profoundness,
And stand too much on seeming.
If arts and schools reply,
Give arts and schools the lie."
,,,

There are several who post here who aspire to these jousts at
comfortable conformity, but they wilt on the occasion. (maybe a touch
of Oscar Wilde in that)

Not yet to threescore, but still an arrogant fool. ;-)

Before you reconnect your lambda/2 longer cable, reverse the connections of that cable (hot <-> gnd) at the load end. There ya go. Back to normal.

The mind boggles...

Hi Richard,

No response as of yet. I expect that the GO or GA converged to an unexpected result, which will prompt a response that the FOM is somehow flawed.

Either way, it really doesn't matter much. As Chip pointed out in a recent post, I have put some effort into debunking fractal antennas. Considering the formal responses to my work, the effort seems to be going quite well.

Steve

Hi,
That was indeed a big message. I appreciate you of telling me your expertise and other stuff. The balanced feeding doesnt need a ground plane and hence avoids unecessary current flow in the ground plane. This is one of the design requirements for mobile antennas. Loop antenna made of slot is what i meant by loop slot antenna. I dont know to publish pictures in the group. Kindly let me know.

bye.

Malcom,

My part in this "antenna optimization" challenge is in direct response to Chip's very public request for a debate on the reported merits of fractal geometry in antenna design. He "needed closure" on the issue. I suggested that the debate focus on a specific antenna design problem. My original suggestion was for Chip to use his GO/GA to optimize the performance properties of a small resonant antenna, given certain physical constraints. I would then compare the optimized design with some arbitrary geometry, using the same physical constraints. Chip requested a FOM before proceeding. I provided a FOM and now await his GO/GA design. The FOM is baselined or referenced to a resonant 1/4 WL monopole.

> Best regards, Richard Harrison, KB5WZI

Richard this thread is broadbanding which pointed to broadening
the frquency span of a monobander, this I did by capacitive coupling
of the feed to the driven element.
The thread you are thinking of is where I have a combination of a
loop antenna and a dipole.I am presently making a variation of
that particular antenna which as I mentioned before is a mechanical
challenge.
The posting was to Wes who stated he was having a problem
modeling the broad band antenna which is the subject of
this thread,I felt I owed him an explanation. Your posting gave an
opening to the jackal, Clark, who immediatiatly took the oportunity
of baying at the moon. What I could have done was to send a private
E mail to Wes since it was he who mentioned the modeling problem,
but that would have left me open to serious charges by Clark of
lieing or other likewise charges
Hopefully that has cleared the matter for you and that I have also
nipped in the bud an attack against me again by Clark.
Sticking to the truth will always beat such a person even tho at
the time the admission was and is personally embarassing.
Best regards
Art

Hi Fred,

Even here, that one is becoming stale. I especially enjoy Boswell.

From "Boswell's Life of Johnson"
"Boswell: 'But, Sir, does not Rousseau talk such nonsense?'
Johnson: 'True, Sir, but Rousseau knows he is talking nonsense,
and laughs at the world for staring at him.'"

We have our own pale imitations of Rousseau too. ;-)

>

My point was that standard PVC insulated 'telephone wire' is a poor choice for RF use. This is because the PVC insulation will absorb the RF causing very high loss. In my case I was using high enough power that there was enough heat that the insulation melted. What I was experimenting with was a compact quad antenna that had a length of twisted pair as a loading capacitor--a high RF voltage was present. Certain frequencies may be worse than others, but I would not recommend it at all for transmission lines. It may be OK for low power temporary antennas but is typically too soft for anything permanent.

RG-174 would be fine. If you don't use more than 2 or 3 feet of it!.

Guess I could have been more clear on my point, Richard.

What I was refering to was the fact that, in my experience, most people think that 'digital' has simpler rules than 'analog' simply because it is nothing but 1s and 0s. As I myself have found out (the hard way!) the best thing to do is to treat digital as if it was RF.

Dear Nick,

Feeding badly mis-matched antennas with coax is a bad idea. The losses in even good quality coax escalate rapidly when operated at high SWRs. The matching unit may present a good 50 ohm resistive load to your rig but the feedline will still be running at a high SWR. If the built in ATU wont match it, it probably means that the aerial shouldn't be fed with coax.

The manual for the MFJ is here
http://www.mfjenterprises.com/man/pdf/MFJ-914.pdf

It is as uninformative as most MFJ manuals.

From the operating instructions I would expect to see 3 fixed caps and a coil tapped in three places inside. It will put these either in series or parallel with the antenna. It may be all caps three put in series, three put in parallel.

This page has a little more info
http://www.wb0w.com/mfj/manuals/mfj914man.html

There are some pretty poor/mixed reviews on E-ham

http://www.eham.net/reviews/detail/884

I'd say you'd be better off getting a proper ATU and some ladder line.

I'd strongly recommend the SGC 230 but that may be too costly for your plans.

just my tuppence worth

Hi Tom,

There's no dispute Johnson could be an ass, as you put it. With your
regard for female perspective, Johnson was asked to comment on
infidelity and why there was a difference in the perception between a
straying man, and a straying woman:
"The difference is boundless. The man imposes no bastards
upon his wife."
Reported singly, and out of context with the times, this remark stings
our PCness, but for the titled (Johnson's patrons), family line is a
very important thing. One need only look at the monarchy and their
anguish of blooded lines.

Boswell, on the other hand, also squirmed from the rigid theology. In
his voice:
"Here it may be questioned whether Johnson was entirely in the
right. I suppose it will not be controverted that the difference
in the degree of criminality is very great, on account of

consequences: but still it may be maintained, that, independent of moral obligation, infidelity is by no means a light offence in a husband: because it must hurt a delicate attachment, in which a mutual constancy is implied...."

Boswell on more than one occasion would come up against one of these moral knots he found in Johnson. And on every occasion he would draw him out for a fuller discussion. Those conversations reveal a more intricate web of morality deeply rooted with the greeks (a classical training), heavily anchored in religion, and very aware of class. On several occasions, Boswell could pull Johnson his way with logic, wit, and being right. Johnson revered right; but he would play the devil's advocate to prove the faithful acted without faith.

"It is more from carelessness about truth than from intentional lying that there is so much falsehood in the world."

There's also no dispute of Johnson's talent that went beyond cleverness (is cleverness a fault?) and he was considered a sage long before Boswell's reporting - which I think you are confusing with the man.

Hi Jim,

OK That I can relate to entirely.

When I was designing the Black Box, I was reviewing the specifications for all the airframe sensors I was monitoring (through 600 individual connections). Among them was the spec for the tape head that recorded the data and that drew my attention to the last generation design for the tape deck. The specs allowed for a terrible bandwidth (not usually found in the head specification, but this was cobbled together paper-work).

It was a simple affair (not part of my job as it was 'plug-n-play') and on inspection I found the head circuitry lacked a bias oscillator. I asked the designer about it.

"Bias oscillator? What's that?" came the reply.

I explained how it boosted the fidelity of recording and thus allowing for a squarer wave recording.

"Don't need it, we are recording digital data, not Hi-Fi."

I never penetrated that iron curtain.

Hi, Richard,
this probably isn't the proper place to discuss Samuel
Johnson, but of
course he did a great service to the English language with his dictionary, and
his
writing, but Boswell, in the example you cited, could have pointed out to
Johnson
that a straying man may not impose bastards on his wife, but he certainly may
on
someone else's wife. You may be right, that I'm confusing Boswell's depiction
with
the man, but I think that, in the main, Boswell did a pretty good job.

> because that is where the highest voltages occur.

I'm sure the whole antenna contributes to the overall radiation, but I think there are cases that point to the "high current" section as being fairly important to the overall efficiency. If what you say is true, there would be no advantage to raising the coil up towards center of the whip, instead of a base load. But in cases of mediocre grounding, it does seem to make a difference. Not to mention the improved current distribution. I've always found this to be quite an improvement over a base fed on the lower bands. In the case of the sloper, I think elevating the high current point does reduce ground losses.

But on the other hand, I don't worry so much about the high current section, that I ignore the high voltage sections. IE: 40 ft high dipole vs 40 ft high inv vee. Yes, the high current section "apex" on each of these antennas is at the same height, but I've always had the best results with the flat top dipole where the whole antenna is up in the air equally. have an Icom 47A 440 MHz mobil radio. This radio is about 15 to 17 years old and still working. I contact ICOM and they say it will take over tow weeks for them to research the info for me.

Does anyone here knows where the Discriminator output is? I need to know where the audio discriminator is located so I can add a sampling simplex autopatch into it.

If you know please email me directly... n7ym@n7ym.net

Thanks

Unlike your designer, I do know what bias oscillators are and what they're for. But like him, I don't understand why one would be necessary or important for digital (by which I mean binary) recording. Why would you use one? Do hard and floppy disk drives use bias oscillators?

Long ago I designed electronics for reading from and writing to a floppy disk, and didn't use a bias oscillator. It performed about at the state of the art at the time, but maybe I was missing something. . .

I told you where to look.

It will appear, and the issue will be non-existent.

The bigger issue--which has been orchestrated (and I use that word correctly) by a handful of 'senior' antenna folks (tell us who they are, Steve) is the dubious issue of 'fractals do no better than other small/broadband/frequency independent/antennas'.

The answer is 'yes'.

Better prepare for damage control gentlemen: hard facts kill poor anecdotal attempts at 'science.'

Enjoy your sense of security on the issue for a few more weeks anyway.

Like I said, you'll know where to look:-)

Have a happy thanksgiving,

Chip N1IR

I posted some information about modeling it with a few conductors a couple of days ago, but didn't mention wire diameter. Generally, when using a wire grid to substitute for a surface (or close mesh like a chain link fence), you use wires with large diameter -- so large that the surface area of the wire is about the same as the surface it's replacing. There's more information about this in the EZNEC manual -- see "Wire Grid Modeling" in the index. But for this model I think really large wires might not be too good an idea, for a couple of reasons. One is that the NEC-2 engine doesn't like connecting a small diameter antenna to huge wires. It can usually be made to work, but you often have to tweak your model while watching the average gain. Another is that the bottoms of the vertical wires are very close to ground. You don't want the ends to be closer than about a wire radius -- farther is better. And I don't think there'll be much difference in results for this situation between moderate sized wires (say, the diameter of the fence supports) and the very large ones usually used for wire grid modeling. If I were doing it, I'd probably try a couple of different diameters and see if it makes much difference.

Heh, heh...

Visiting Chip's pontificaly pronouncements on his "hermetically sealed and highly censored" web site is sorta like dealing with the Sadam Hussein and the Iraqi media in the field of antenna design.

To find the truth, one would have to send UN inspectors into Chip's nominated web site under threat of "serious consequences", and... the possibility of any questions or debate about the challenge in that protected venue would be moot without open debate.

I for one feel that it will only be a "fair debate" if Chip presents his results here for comment and debate on the very forum [USENET NG rraa] where he personally took his and our valuable time to issue his challenge to a debate.

If he can issue his challenge to a debate here, then what gives him the right ask others to see his one sided posts only on his web site?

It would only be fair and balanced for him to post his results here for all to see. He must do so here where the world's most renowned antenna experts can engage in the debate on neutral territory, i.e. rraa is the "no spin zone" for antenna gurus.

But as we all know from Chip's past behavior... that is not likely to happen! Apparently as we have often seen... like the Pontif of Rome, Chip's pontifications can not be questioned!

I for one will never go to *his* site to see just one side of this debate! [Just as I would never go to the Iraqi media to find the truth about Sadam Hussein.] Unless Chip posts his results here on rraa for all to see, comment and debate, then AFAIC he has simply already *LOST* the debate.

Chip, my boy don't waste your time if that's all you intend to do! If you can't run with the big dog's then stay on the porch!

==========

The high current section is no more important than any other section.

It is equally logical (or illogical) to say - when the loading coil is raised further up the whip the voltage above the coil increases, the electric field intensity increases and so radiation from the top portion of the antenna becomes stronger.

What happens is explained just as easily without any reference to current distribution, only voltage.

(In a small way the current-carrying portions ARE more important but only because that's where conductor loss occurs.)

(Not surprising, there's a resistance associated with radiation from the ends of an antenna. Power radiated is (V-squared)/Rrad, where V is the RF voltage at the end relatve to the zero voltage point. For a 1/4-wave vertical Rrad is of the order of 2 or 3 thousand ohms. For a short vertical it can be many kilohms.)

Yet programs like NEC and MININEC depend entirely on the notion that the field produced from a conducting segment is directly proportional to the current flowing in that segment. And, within our ability to measure, they seem to do extremely well at predicting the fields that real antennas radiate.

Thank you, Roy. Reg's comment made me wonder if I understood even less that what I *think* I understand (which is not much).

To the extent that a half-sloper is an odd type of vertical, it seems that a high feed point should help. (Especially if there is some clutter around the tower base.)

I am getting a strong impression that half-slopers are in the realm of "fool with it until it works well enough" instead of "calculate the right answer and build it." I accept that modeling could be very helpful, but it would probably be necessary to accurately model the tower itself, whatever loading is above the feed point (I should not have called it "counterpoise" in my initial query), a fairly accurate description of the ground and radials, whatever other feed and control lines are also present on the tower, and the characteristics/position of the sloper wire.

Regards,

Bill

Source record: 130550

I tried a half-sloper a long time ago, when the concept first showed up. At the time I didn't understand much about antennas, so was surprised to find that the wire wasn't really the antenna -- the antenna is the wire, the support, and in some cases the feedline, all in about equal measures. What's happening is obvious now.

Whatever current you put into the wire portion of a sloper, an equal current has to come from somewhere and flow into the other feedline conductor. If the support is metal, the current flows in the support. And if the support is about the same length as the wire, it'll contribute about the same amount to the radiated field. If the support isn't metal, then the necessary current will flow along the outside of the coax, and it will be the other half of the antenna. So a sloper depends as much, or more, on the support, its length, diameter, and how it's grounded, as it does on the wire which most people think of as the "antenna". The tower isn't a "counterpoise" -- it's an integral part of the radiating antenna. A half sloper is essentially an inverted vee, with one leg being the wire and the other the tower. But if the tower is around a quarter wavelength high and grounded, it'll behave very differently from a conventional inverted vee.

Because of the variables involved, it would be hard to predict how a particular half sloper would behave without modeling it. This is one of the places where modeling is very useful. With modeling, you'd be able to get a good idea of what's happening and what you'd need to do to get the results you want. Without it, you'll be doing a lot of guessing and blind experimenting.

Barring getting the info you seek, can you tap the audio off the volume pot's high side? This is what I always use when hooking up a TNC to the rig...that way you have a fixed volume level regardless of where the volume knob is set. Just food for thought...

It is basically what was called a ZL Special some years back. It is a short spaced two element beam of basically yagi design.

Both elements are fed. Out of phase from each other. When I was in Germany in the USArmy I had one built for 2 meters. It was mainly used there for a 'fox hunting' antenna.

Brought it back with me, but it got away somewhere.

Bill,

I have used half slopers with success for 22 years, experimenting with wire lengths, top loading, and radials under the tower. I have found that in my installation, 32 - 38 feet up on the tower works well. I have also found that the more top loading you have on the tower in the way of HF and VHF beams, the better the system performs.

I once tried to use a 35 foor push up pole at a field day site as the half sloper support grounded at the base. It did not perform well at all and I think it was because top loading was not present in the installation.

Radials attached to the base of the tower seem to help a bit as I once set up a system where I could disconnect the radials via a remotely operated relay from inside the shack and make A/B comparisons on different bands. Becuase the radials were in the ground and the tower base was also in the ground I suspect that they still had some interaction when disconnected.

Most stations reported a difference when the radials were disconnected, although the difference never amounted to a few db on the minus side, and some noticed no difference. The interesting thing about this experiment was that some stations told me they could definatly hear a difference in the signal with the radials attached, but could not see difference on their S meters. The swr as measured in the shack did change a bit on most bands though.

I also found that no matter how much I tried, I could never get a better than 3/1 match on 75 meters while there was not much problem getting good matches on 160 and 40 meters. While a standard 1/2 sloper on 40 meters works well, A 3/4 wave sloper on 40 worked better.

At one time I had individual half slopers on the tower for 160/75 and 40 meters all running in different directions. I found that except for 75 meters, the angle of the wire can have an effect the swr as measured in the shack.

Presently, I am using the Alpha Delta DX-B ($25 on eBay.... could not resist) and it works well on the 4 bands it is designed for although the best SWR on 75 is about 4/1. On 160 it is very narrow in terms of bandwidth havinf about a 15khz range +/- it's resonant frequency. On the other hand, one wire replaced three. I have worked a surprising amount of DX on 160 and 75 with it, and A very good amount on 40.

These are just my observations gathered after 22 years of use and I do not claim to be an expert of any sort nor do I own any analyzers of computer plotting programs. Just cut and try.

==========
Roy, your (above) statement is fully endorsed.

However I hasten to reassure you I am the last person to attempt to decry the usefulness of your renouned programs. But I have never used numerical computing tools, not even a Smith Chart to prove the laws of physics. They lack any connections. I mention programs here only because you have done.

But I'm sure you would not wish to encourage those who jump to the conclusion that radiation mainly occurs from those PARTS of a dipole which carry the greatest current thus incorrectly conveying the impression that some parts are more important than others. And no-one classifies you as an Old Wife. ;o)

That the programs you mention depend ENTIRELY on NOTIONS (your description) and the imaginations of mathematicians which happen to provide the correct answers as determined by experiment should not be allowed to put the cart before the horse. Radiation came first. The Big Bang? - THEN came the mathematical techniques imported from other fields of application. Mainly Victorian physics and mechanics. And of course the once-ridiculed Oliver Heaviside.

There are other, equally valid mathematical tools for predicting distant radio fields from antenna dimensions. There must be at least one corresponding method which begins with the NOTION of the voltage distribution along a conductor, even no conductor, the etherial fluid.

Current need not be involved. The mathematical process is changed. Should we then jump to the conclusion that radiation occurs mainly from the end portions of a dipole merely because that is where the electric field has its greatest intensity?

To conclude, the radiation field is zero on the surface of a conductor segment regardless of what current may be flowing in it. And radiation occurs by detachment from the near field at short distances from the conductor because of the free-space propagation velocity and the time factor. So the near electric field does not have sufficient time (as set by frequency) to collapse on itself at the instant of zero voltage on the antenna. It becomes detached, flies away. We then, for convenience, change

its name to the radiation field.

I could have said, equally truthfully, at the instant of zero current in the antenna, the near magnetic field at short distances from the antenna wire does not have time to collapse to zero. So it also becomes detached and flies away, for ever, in phase with the detached electric field. Note that the near-field magnetic and electric components are at 90 degrees to each other and so no power is involved except the relative small fraction lost in conductors and what is radiated. The small loss is related to antenna Q and bandwidth as discussed recently.

And I've gone to this great length just to say greatest radiating efficiency or a desired radiating pattern do not always occur when the current carrying portions of an antenna wire are at the highest point of the antenna above ground. All parts of the antenna are of equal importance. But not as much as may be supposed - just get some amps and volts as high in the air as possible and away you go distant places.

PS: I've just noticed in the small print the contents of this bottle of Californian (Rivercrest) white whine are measured in milli-litres. Is this another sign the US is finally going metric or is it merely because it is labelled for export?

Reg, G4FGQ.

Wouldn't we all take the pointy ends of antennas (and voltage) 'more seriously' as a contributor to radiation if these ends looked more like a capacitor (increased surface area, for the voltage) and less like a conductor (a wire, for current where there isn't much) ?

I suppose that one could create an antenna that worked 'more on voltage than current' (excuse the wording), but it would require a lot more material and would tend to blow away in the wind.

Current and voltage are simply two handles on the same EM crank. The current handle is more convenient.

Reg, if one models a 1/4WL Inv-L, 1/16WL vertical and 3/16WL horizontal, the horizontally polarized radiation and vertically polarized radiation have about the same dBi gain even though the high voltage part of the antenna is three times as long as the high current part.

Hi,
I want to project Yagi for 460MHz using Quickyagi 4.0.
The boom for this antenna will be made from nonconductor.

I wonder if calculations for this type of boom will be accurate (using
QuickYagi)?
I've set "Options->Element Compensation->Boom Compensation"
to "Element placement = On the boom" and "Boom type = round".

Thanks in advance,
Rob

Beat me to it, Roy.

Of all the magnetic recording formats I have worked with/on (5 track reel, 7 track reel, 8 track reel, 8 inch floppy, 5 inch floppy, 3 inch floppy, 1/2 inch cartridge, big hard disc, little hard disc) none had bias oscillators. (hmmm. Wonder if I could renew my Trident disc repair certification? Its a bit out of date---like 20 years. Is Century data still in business?)

As you pointed out they aren't needed for binary data. The magnetic coating is specially formualted to be saturated. That is, the magnetic field is all one way or the other. It also has quite a bit of hysterisis when switching.

Never worked with analog recording, but I would guess that the magnetic coating is formulated to minimize hysterisis. What is actually put on the tape is the 'bias' signal, which is modulated (FM?) with the analog data.

3331. Making my own 10 meter antenna (Newbie)

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-27 13:23:13 UTC
From: dgilbert@nascospg.com
Message-ID: <a235b6a6.0211270523.208bb511@posting.google.com>
Source record: 130470

I have been into 2 meters for a few years now and am thinking of getting into 10 meters. I was wondering the feasibility of building my own antenna to be put atop my TV antenna tower in back of my house.

I work on lots of metal projects in my garage and have a fair amount of tools including a mig welder. I also have access to lots of new steel square tubing as well as solid round steel from about 1/4 inch diameter up to 1/2 inch or so.

Would it be possible to make my own whip out of steel as an antenna? What length would be the best performance on just 10 meters? DO I need an antenna tuner?

Sorry for all the questions, I am relatively new at this.

Doug: It was written up in the RSGB VHF UHF manual 4th edition. I think
that it was favoured by the Europeans and your best bet would be on some of
their sites. Especially some of the UK sites. Keith, VE3JKC.

You're starting from such a basic orientation, you might go to http://www.arrl.org and order their book, "The ARRL Antenna Book." It has great numbers of homebrew antenna projects you can apply to 10 meters or any other band.

Thank you, George. That is the type of practical information I was looking for. Based on reports like yours (and a very vague "hunch" of mine), I will try placing the half-sloper at the top of the middle section of the TX-455. That will allow the top section and the mast/boom of the quad to act as loading --- although I suspect that term might not be 100% appropriate.

Most write-ups mention that changing the wire angle usually affects the feedpoint impedance.

You have obviously done some experimenting. Have you ever tried using two wires of slightly different lengths for the same band? Say, one for 3.6 MHz and one for 3.8 MHz?

With the narrow 160m bandwidth and the best match on 80 being 4:1, I assume a lot of your operation is at rather high SWRs via an antenna tuner. Have you had any significant trouble using 500W - 1 KW? What type of coax are you using? (I am planning on using RG-213.)

Thanks,

Bill

If all parts of an antenna radiate equally, shouldn't an antenna that is half vertical and half horizontal radiate equal amounts of horizontally and vertically polarized radiation?

One thing you could do that is very quick, cheap and inexpensive is buy a mobile whip CB antenna, cut it slightly shorter for 10 meters, then mount it with 3 or 4 sloping radials. I've done this with good results. You'll never have to worry about the wind.

If you're in the mood for something a little more elaborate, being a metal worker and all, you might be interested in a 3-band trapless vertical I put up on the web a few months ago.
http://dt.prohosting.com/hacks/antenna
It's a bit more trouble to make but it works on 10,15 and 20 meters that I know of. Embarrassingly, I still have no idea what it does or doesn't do on 12 meters or 17 meters. I do know that it doesn't like the CB band when tuned for 10,15,20.

Experimenting with antennas is just plain fun, and with some of the cool software you can get these days, you can have a reasonable idea of what is worth trying to build. Antennas for 10 meters don't have to be very large, so you don't need a lot of room or a lot of materials to make some pretty respectable performers.

Have fun and good luck!

Dick:
Two possible approaches. One is to make the conductor larger and shallower radius buy putting a conductive ball on the end of it. The other is to extend the insulation well beyond the conductor, although the poly. will break down fairly quickly. You need a bottle of the old General Cement Corona Dope which was used on TV high voltage problems. Or Glyptal. Or any high voltage varnish. Lots of coats.

Good luck.

Roy Lewallen, W7EL wrote:
Why do you use one (a bias oscillator)?"

A magnetic tape only reproduces from magnetized areas. How small and distinct these areas are determines the information on the tape,

Recording quality depends on the equipment and how it is used. Tape speed and track width affect quality.

High frequencies are most likely to be distorted in the recording process. Whether an area represents a one or a zero has to be interpreted in recording and reproduction. The sharpness of determination depends on high frequency response.

Very high frequency bias is added to a tape to cut distortion of the signal. The bias assumes the distortion, not the signal.

Bias level is optimized for best h-f response.

Bias and compression techniques can produce quieter and more distinct signals than digitizing alone. I`ve read this from sources I consider reliable, but cannot attest from personal
experience.

Best regards, Richard Harrison, KB5WZI

Hi Doug,

I've built and uised the HB9CV antenna on 2m and also some time ago on 27MHz. It's basically very similar to the "ZL Special" both in function and performance. The main advantage is that you get some directivity without much boom length. This makes it a good antenna for portable use.

The 2m versions are commonly used for DF, built from stiff wire. My 27Mhz version was built with aluminium salvaged from an old 3 element beam. Performance is nowhere near a yagi, the main lobe is very wide, but that's the price you pay for a short beam.

Kind regards

It's possible, but steel is not the best conductor for rf, and it will
rust fast. I would try to scrounge some aluminum. Actually, probably
the easiest way to build a 10m vertical is probably to find an old
junk CB antenna and retune it for 10m.
But if you can't find one, 1/4 wave ground planes, 1/2 wave verticals,
or 5/8's wave ground planes are all easy to build. I'd go with the 1/2
wave if you don't want radials. MK

Bill,

You are correct when you say that the wire angle affects impedance and
it is an accepted way to tune a half sloper. The height above ground of
the end of the wire also can make a considerable difference in tuning,
in my experience more so than the wire angle.

Your comments about two wires cut for different parts of the band is
interesting. Although I have never done it, I have seen it illustrated
in the ARRL antenna handbook (1988) and I think it is mentioned in
W1FB's antenna book that was an ARRL publication back in the early 90s.
It is claimed that you get a 2/1 or less SWR across the band using this
configuration on 75/80 meters. Sounds like one of my next
projects......

Yes, I do use an antenna tuner on 75 and on 160 if I make large
excursions. I have no problems with my 125 watts using a Drake MN4C tuner
and I do not need a tuner on 40 where I get a 2/1 or less swr across
most of the band. My tower and beams top out as 40 feet and I guess it
is possible that if I was able to hang the sloper from a higher tower it

might positively affect 75 meter SWR. I am using 50 feet of RG8/U (tower outside the window, shack just inside... no need for long runs) and I don't think that even at a 3 or 4/1 SWR on 75, I am suffering excessive loss.

If you do not want to go the Alpha Delta DX-B route, just try a single 1/4 wave wire for a given band, insulate the radiator and clamp the coax shield to the tower leg and see where it tunes up. I have noticed that 40 meter length comes out close to formula predictions but 75 meter length is usually shorter than what you would expect.

These are good performing and easy antennas to build and install.

Good luck with your project

Hi Roy,

I will expand on bias virtues and uses.

The bias adds a self demagnetization (de-gaussing) component to the head's operation. Now this may sound counter-intuitive, but heads suffer from becoming magnetized by the constant flow of tape past them. This in turn creates a situation where the head then erases some of the signal being recorded, and worse, erasing content when it simply is reading. Through the addition of the bias, the head is constantly being de-gaussed at a frequency that is higher than the head's capacity to record (the frequency never becomes a component of the recording).

Insofar as fidelity goes, the oscillator adds a modulation product to the content being recorded, but as the tape draws along and away from the gap, the bias continues at a declining level (the bias modulation cannot persist through the recorded waveform) in comparison to the data being recorded (much longer wavelength). The net result is that the head's geometry (specifically the wavelength relationship of the gap) ceases to impose the modulation and the data amplitude begins to smooth out by the time it is impressed upon the tape. In this way, the modulation product forces the electronics into a linear portion of their operation that would not normally be attained except through the loudest of signals in the data. Thus the bias also works in the conventional sense of setting an amplifier's working region.

Without the bias, the high frequency components of the data are attacked by two processes, loss of fidelity through poor reproduction (a biased recording has vastly more bandwidth) and degradation through magnetic artifacts (as already described). It is largely the

artifacts that seal the fate through a poor signal+noise/noise ratio combined with restricted bandwidth.

I must add that this tape transport ran at far slower speeds than most here have ever used (7/8 ips I recall vaguely).

My background began in linear design, and I was move by market forces to do linear interface (tedious digital design is best left to computers). As the linear traditions faded from the academic perspective, it began to show in the quality of linear designs by solely digital trained designers - not too hot. True, they could burn a PAL, or design a mask (something for which I had absolutely no interest), but when I pointed out Shannon's law about data degradation and noise, all I got was "We aren't recording music - just digital data."

This came at a time when I was looking over their shoulders watching them trying to tease data out of the noise of a KLM jet recording that took an unscheduled dive into terra firma. This was a case where KLM could not read their own data and sent it back to the "factory" for sifting. I could only shudder, not only for the sake of those who bought it (literally and figuratively), but also for the lack of knowledge that could have increased the data throughput.

I was also solicited to review the Flight Data recorder data for TWA 800. The concern there was that the few jangled bytes of data appearing at the point PRIOR to air-frame breakup could have been evidence of missile strikes. Yes, it is arguable that they could have - but that noise was also within specs (terrible as they were). The report submitted by all the agencies had some rather bogus interpretations entered into the analysis to cover the critic's concern. It didn't satisfy them, and the interpretations certainly were not science nor engineering.

This last, in fact, brings us back around to the current World issue of Ossama, Saddam, and such. The conspiracy theory about missiles taking down TWA 800 had a reasonable genesis: we had shot down an Iranian civil airliner over Iran back during the first Iraqi fight. TWA 800 was payback and reported as such throughout the world - except here of course (not an uncommon insularity in our news). They also had the technology to do it, after-all Poindexter and Ollie North had sold them the missiles capable of taking down TWA 800.

So, we have motive, opportunity, ability, and conspirators eager to supply them. Put such patriots as Ollie and Pointdexter (both felons) against the wall? No, it was simpler to say a spark did it (never happened before, and hasn't happened since) in the most safe of aviation fuels. It pays to have equal minded friends in high places.

Hi Richard,

I did, but no one seemed to heed that in the transition from data to
tape, they had forever left the digital world behind to enter the
noise and distortion of a linear (tape) real world.

Sure it worked, but they failed to analyze: how well? The product in
the marketplace and in constant use proved them adequate - until KLM
(see other posting to Roy). It is a bit specious to say it was a
suitable design, when 99.999999% of the data is never seen, much less
analyzed. It is ingenuous to say it was suitable when your customers
who encounter that 0.000001% of the time have to send their tape back
to the "factory" for data cleaning, sifting, and download.

Hi Jim,

I've worked with all types of magnetic storage (even bubbles) and have calibrated NAGRA recorders. I once constructed a length of tape with a fixed frequency, and had to demark it by scraping off the coating (for a precision fixed interval) at both ends. Even with the tape clear (literally) of oxide, there was still a measurable signal. That idea was a goner.

The Bias is about 30-40KHz and is impressed on top of the data - not mixed a la FM. You are thinking about VCR recording. One method used by one of the big Reel-to-Reel builders (Roberts) was called the cross head bias. They used a separate bias head sitting opposite the record head. For more discussion of the bias, consult my posting to Roy.

You are also comparing Digital recorders (multi-track, with one bit per track) running at elevated speeds (surely faster than 7/8 ips) to an 8-track cassette deck quality design (less the quality of HiFi much less stereo and only one track, unfortunately). You might also reflect back to the service required of Digital recorders (like head de-gaussing and tape cleaning) for more comparisons where the flight data recorders see none of that activity.

Use stainless if you want to work it yourself. As 10M is a big band,
one man's advice about how long is another man's SWR.

The better part of designing an antenna is so you won't need a tuner
;-)
... but that doesn't always happen :-(
>
>Sorry for all the questions, I am relatively new at this.

Hi OM,

As the others have suggested, CB products can be used for stock, or
simply take a picture and reduce the dimensions to 10/11th's. This is
the best method for complex designs like a yagi. I've whacked down CB
whips for 6M - simple, and quite stiff.

Or presuming a simple vertical, do it the old fashioned way: nibble at
the tip till your SWR drops (how I got to 6M). Be careful if you
undershoot the minima, and it starts to climb with that last snip -
just let it be (and that will teach you not to take big nibbles the
next time).

This was for mobile operation, and I had nothing else to vary for
tuning. With your position up higher and on a tower, you can also
play with the angle of the ground plane (radials' angle to the
horizontal) to make up for marginal vertical heights (the one you

nibbled too far). You might want to simply tack something together and tune it first as a template for your more serious effort. There will be little performance variation between them.

Hi Roy,

Do they have bias oscillators, I haven't the vaguest idea.

The period of history I am speaking of was in an age when 8 inch
floppies were standard and data at home was stored from a VIC-20 to a
cheap tape deck (which had no bias either, but ran at 3.5 ips).

Yes to both. BUT here's some things to consider. Steel is heavy and rusts easily unless painted. If the paint chips, it still rusts. Aluminum is a good choice as it doesn't rust and only weighs about 1/3 what steel weighs.

If the antenna is the correct design and length for the portion of 10 meters that you will be using, you won't need a tuner. As one of the others has suggested, get the ARRL antenna book. Also get an SWR meter and learn to use it as you will need this to determine if your antenna does match your radio for the desired frequency.

3363. Skin effect - a follow up.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-28 02:09:44 UTC
From: amfowler@melbpc.org.au
Message-ID: <3de679cc.11108902@news.melbpc.org.au>
Source record: 130501

Skin Effect.

I came late into this discussion and didn't realise that
there were discussions on two quite different applications
of skin effect - 1. The use of a metal shield to stop r.f.
energy entering (a screened room) and 2. The current
distribution in a conductor carrying A.C. at any frequency.

1. No comment.

2. I said in an earlier posting that the current
flowing in a conductor decreases logarithmically from the
surface towards the centre of the conductor. I should have
said decreases exponentially, as others have pointed out.

I must stop making comments late at night when I'm
tired and not thinking clearly.

I've put a short note and a drawing that shows the
current distribution on a circular, solid, copper conductor
for a number of frequencies and conductor diameters. You
will find it at
http://member.melbpc.org.au/~amfowler/skinefct.htm

From an earlier posting:

>>Suppose we are talking about a length of 16 guage
>>1/2 in diam copper tube whhich has been wound into
>>a coil.

>>If the ends of the tube are open,it does not
>>matter if you connect the lead to the inner or the >>outer surface of the tube.

>In practice that's true. In order to make a
>connection to the inside, you have to poke a wire
>inside the tube. Then you have a co-axial line
>inside the tube which will support current flow on
>the inside. You'll end up with essentially the
>impedance of the short length of co-ax in series
>with the coil since this is the path that the
>current on the inside will take to the outside.

You are suggesting that the current will flow from the
connection point back to the end of the tube along the inner
surface, across the thickness of the tube, then along the
outer surface.

Think about this carefully. In effect this path would have a significant impedance.

There seems to be a misconception that the current cannot flow directly from the point of connection inside the tube to the outer surface.

Think about it this way. Take a long straight conductor carrying an r.f. current. Now disconnect it, make a small hole in a piece of copper sheet, slide it along the wire and solder in place (both sides. Connect the wire back into the circuit.

Now does the current flow up to the sheet, flow out over one side of the sheet, across the edge, back down the other side then continue along the wire, or simply continue along the wire, through the disk and out the other side. Why?

Alan

I'm not familar with the program but it should have an option for
conductive vs. non-conductive boom. That has a non-trivial effect on
element length depending on how the elements are mounted.

W1JR and K1FO wrote some great articles in Ham Radio and QST on the
subject of yagi design back in the late 80-'s to early 90's. One or
the other addressed this topic.

---------- Snip Here ----------

Wires 1-16 are the director 17-32 are the reflector. Wire 33 is 100
wavelenghts away to act as end point for the transmission lines.
The first 4 Transmission lines are equal length stubs on the Director
the next 4 are on the reflector. The Spreader length is 10 feet. All
the wire data above is in mm. There is a scaling card to reduce it to
meters. The only parameters that you can play with is the director and
reflector transmission line lengths.

Questions: 1) Is the transmission lines stub properly modeled.
2) Is the specification of the wires close to the spreader
violate any NEC rules
3) Is the model adequately segmented.

Observations: 1) Changing the Director TL length has very little
influence on forward gain. It has huge influence on the input
impedence.
2) Changing the reflector TL length changes Gain, F/B
ratio as well as input impedence.

Don't know about the Bandwidth behaviour of the model.

Here is some results for your enjoyment

Dir TL Len	Ref TL Len	Fwd Gain dbi	F/B Ratio	Input Imped. R	Input Imped. X	FOM
1.350	1.560	7.6	6.9	31.9	42.9	44.19
1.350	1.580	7.5	9.1	40.7	32.2	46.13
1.350	1.600	7.3	11.6	52.5	22.5	47.87
1.350	1.620	7.0	13.9	67.2	14.9	48.33
1.350	1.640	6.7	15.1	84.3	10.8	46.97
1.350	1.660	6.4	14.8	102.5	10.9	44.57
1.370	1.560	7.6	6.9	32.1	33.3	44.61
1.370	1.580	7.5	9.1	40.9	22.5	46.82
1.370	1.600	7.3	11.6	52.7	12.7	49.23
1.370	1.620	7.0	13.9	67.6	5.2	48.86
1.370	1.640	6.7	15.1	84.8	1.0	47.05
1.370	1.660	6.4	14.7	103.0	1.1	44.60

The FOM is based on Gain, F/B ratio and return loss.

Enjoy
Regards
Nat AB6SJ

Interesting, thanks. For clarification, it should be stated that the figures represent U.S. licenses, not world-wide. I wonder what those numbers look like.

I inadvertently responded a short time ago to such a post. I will ask everyone responding to check the cross posts to a ton of other newsgroups. This might be ok for some of the amateur groups, but I doubt rec.radio.cb is too interested in this.

Thanks & 73 from Rochester, NY

There's very good information about the effects of conductive booms and clamps in Leeson's _Physical Design of Yagi Antennas_, from the ARRL.

If making the boom from non-conductive materiel, you want to use
the free-space measurements. Set the boom compensation to zero...

Hope this helps.

>. . .

1. If these are intended to be short circuited stubs, they are properly modeled.
2. No, the model looks fine. The EZNEC Average Gain check shows 0.0 dB, which is excellent.
3. The model needs more segments for best accuracy. The way to test is to increase the number of segments and see if the answer changes. You'll find quite a noticeable change in impedance and front/back if you increase the number of segments in the long wires to 21. Increasing to 33 makes a much smaller change, and there's hardly any change if increased beyond that.

I've converted this file (with original segmentation) to EZNEC format if any EZNEC users want to take a look at it. You can download it as Pfeiffer_Quad.EZ and accompanying Antenna Notes file Pfeiffer_Quad.txt from ftp://eznec.com/pub/. There are too many segments to run with the demo version, but demo users can view it with Antenna View. Because EZNEC has shorted and open stubs as modeling components, wire 33 wasn't necessary and was deleted.

Actually took the easy way out and melted some insulation from another piece of coax over the tip of the one functioning as the tuning capacitor. If that fails over time the RTV or Corona Dope ($7.00 per bottle) will be next.
Thanks to all that responded.
Dick N3HKN
PS: The 3.5ft square loop using 1/2inch copper pipe works quite well. Before the corona I had it up about 15ft, 10 ft from my GAP vertical, and it was usually equal to it given the directional characteristics of the loop -20M.
See http://www.standpipe.com/w2bri/ for construction details.

> Get a General Electric Superradio. About $50.

Or an old AM/FM car radio, about $10. Some even have AM Stereo. Needs a good, quiet power supply of course. And speakers. And a short wire antenna. You know it's working when (at night) you can't find an empty channel on the AM band.

Try the web page, http://www.ccrane.com

Call the folks there. They specialize in long-distance AM radio reception, and have a good selection of radios and antennas that would be helpful to your situation.

When a license number is quoted, you need to know what the total consists of. Does it include club and other group licenses? Does it include all FCC ham licenses, or only those in the 50 states? Does it include expired licenses that are in the grace period, or only current, active licenses? How about RACES licenses, which FCC seems to be phasing out?

A very useful source is:

http://www.arrl.org/fcc/stats.html

which lists licenses held by individuals in the US and possessions/territories. They are broken down by state/posession and license class, and are derived directly from FCC data. Updated every day or so, and the date is given. Only downside is that only current data are shown.

The thread "ARS License Numbers" includes bimonthly updates based on these numbers. The current total is about 685,000

>That leaves AH0A, who calculates that the average age of a ham license
>is less than 60 months (currently about 57), and that's a critical
>figure for licenses which are renewable every ten years. It means
>that the total number must eventually decline, no matter what the
>short term fluctuations may be.

How does the average age correlate to anything related to growth or decline in totals?

The license term is 120 months. The midpoint is 60 months. Renewals can only be done in the last 3 months before expiration, unless you let the license expire. So a "young" database could be caused by lots of new licenses.

But in fact the "average age" is affected by many factors. The number of new licenses, and expirations/cancellations, rises and falls dramatically (see AH0A data on "new licenses" and "expired licenses" for some examples). An upgrade or address change does not generate a renewal unless the license is within 3 months of expiring, but a vanity call generates a renewal regardless of the license term. Vanity call rules changes in 1994 generated a surge of vanity calls, skewing the renewal dates. The 2000 restructuring generated a surge of upgrades, many of whom got vanity calls.

What's most important is the long-term picture rather than short-term variations, but that requires data keeping over long periods. With the demise of the Callbook, that job got harder.

Also, license totals themselves are not really the issue. What matters is the number of active hams on the air, and what they do with their license privileges.

Good on you Alan.
May I interupt before Roy's response.
If one uses a metal conductor with a thickness of only
the skin depth of a 'normal' conductor (this conductor being
a skin or shell on a insulator)what actual changes if any occurs
with the density chart of current flow? Other comments?
Best regards
Art

Worse come to worse, you can replace the original driver setup
with a gamma match; "borrow" a design from a handbook.

All good suggestions. The GE Super radio is very good and perhaps the
best bargain in long range AM radios. It is usually available locally
and Radio Shack markets a re-branded version of it that is in every
Radio Shack store in my area and most likely where you are.

I am presently using a CCrane CC Radio which, IMHO beats the Super radio
in most respects. However it is over 3 times the price but again, in my
opinion, worth it. I have also used car radios in the past and these are
almost uniformly good inexpensive(sometimes free) alternatives. It seems
that Ford and Chrysler radios from the 60s, 70, and 80s do the best job.

Check out the CCrane company at: http://www.ccrane.com Lots of good
stuff there.

I've been considering a BIG loop... full-size on 160 meters. An antenna engineer friend was the first to warn me about the corona thing. Apparently, a loop that long can generate huge voltages in just a gentle breeze.

His suggestion was to feed it with a center-tapped transformer or torroid and ground the center tap. I have not looked into that idea so I just toss it in here for what it's worth. Sounds reasonable to me.

Not a bad start Thomas. One problem is that AM radios are usually hardwired to a ferrite rod antenna. The long wire will definately be better but you need either a radio with external antenna connections or you need to go into the radio and create your own by disconnecting the ferrite and adding components to couple the new external antenna.

An external antenna tuner will also help greatly. Take any design from the handbook and build it on the cheap since you do not need power handling capabilities. Commercial receive only tuners are also available cheap.

Changing radios as was earlier suggested is a good idea also. The GE Super was one of the few AM radios with a hot front end. Any of the SWL receivers such as the Yaesu FRG-7, Drake R-8, Grundig, etc etc will also do fairly well and give you additional entertainment listening to the short wave broadcasts.

Ummm, not quite.

May, 1990 Philippine Airlines center tank blew up.

March, 2001 Thai Airways center tank blew up (on the ground).

On Nov 23 and 24 the FAA issued emergency AD 2002-24-51 and AD 2002-24-52,
applicable to all Boeing Model 737-600, -700, -700C, -800, and -900 series
airplanes; Model 747 series airplanes; and Model 757 series airplanes.

The problem is related to extreme localized overheating of particular
fuel pumps.

Art:

Carefull Art, although he has an interesting Web site, Alan is located in
Oz!

Down there in Oz, somewhere below the equator, guarded jealously by Old King
Neptune, water circles around in the opposite direction due to the Coriolis
Force when going down the drain, cyclones circulate in the opposite
direction to what we are used to, and you can't see the "Pole Star" for
night sights, and so the electrical skin effect may also be similarily
affected.

Hi Rob,

run your final model again with a NEC2 engine f.e. 4nec2 (
http://www.qsl.net/wb6tpu/swindex.html)

or MultiNEC

www.qsl.net/ac6la

it is free and more reliable.

With a non conducting boom element correction is not necessary.
You may need a slight correction due to internal deviation of the software
if you have a highly optimized version (see SM5BSZ page).

This last question went un-responded to (even when it was relevant to the discussion), but we thank Richard Harrison for the inclusion of these particulars.

Of course, by reviewing your page offered, it is obvious that having read 147 papers on the subject you are no stranger to this at all.

For those interested in the science (or simply want to look like a scientist by using a formula) consult "Reference Data for Radio Engineers." "Fundamental of Networks," "Skin Depth." Table 2 offers a Skin-Effect correction coefficient A for solid and tubular conductors. As the math is heavy in greek symbols whose roots are taken, I will skip their duplication here. However, on review of those tables, it seems it would take an extreme example to force a variation of greater than 2% from the expected.

Alan, given your readings, I have a question on a comment dropped into one of my references ("Engineering Electromagnetics," William H. Hayt) relating not to the depth, but rather the depth propagation for a 1KHz excitation. What do you have to offer in regard to:
"The velocity of propagation for this example is only 13.1M/s, or about 30MPH. This is a far cry from the velocity of propagation of a plane wave in free space. Associated with this small velocity is an extremely short wavelength of 1.31cM or about 1/2 inch. Again the comparison with free space is astonishing, for the wavelength in free space corresponding to a frequency of 1,000 cps is almost 200 miles."

I find it amusing that where science is denied, it has more spectacular effects than those claims dreamt up through musings and imaginings.

Hi Peter,

Gad, don't go there puleez, next we'll hear is that the science of
skin effect is astrology. I don't want to have to correct those
misinterpretations of the implication of the trine aspect of Jupiter
(a benefic) in the IV house and Aries rising in a natal horoscope.
The next thing demanded would be a new depth penetration correction
table for the dawning of Aquarius. ;-)

Hi Nat,

Between your generous publication of the particulars, and Roy's effort to make it accessible to us all, you have offered an interesting antenna that relates to several threads that have been running in this group recently - to wit, loops, stubs, and small form factor.

Given the results of modeling this, it appears to be a nice performer (7.27dBi) with a bandwidth running from 14.145 to 14.285 MHz (an analysis you desired).

For what it's worth. I use a mag-mount cell antenna for receiving 30 to 174 scanner in the car. Works good in a rural location.

Hi Nat,

I just compared this to another (miracle) antenna designed to the same
band, but with 13 elements! It proves to have more gain, but less
than 4dB more for all that aluminum put into the sky.

The NBS yagi compared to that same 13 element yagi comes in less than
1dB behind - to think, less than 1 db for 10 more elements.

Nonsense: that advice would be relevant for a TRANSMITTING
antenna. For receiving, a ferrite rod or tuned loop is far better
than a random wire. No matter how high or long it is. Unless
it is a Beverage antenna, in which case it should be a long
as you can, but as LOW as you can (even laying on the ground).
In no case AFAIK is ground particularly critical for receiving.
Been there, done that.

Worst case, you simply wrap a few turns (10-ish) of wire around the ferrite rod and connect the random wire to one side and a ground to the other. Whether or not it actually helps reception is another matter.

Very funny Peter, but Alan appears to be a very knoweledgable person
regarding skin effect and I am sure he has taken that into account. I
for one want to take advantage of his knoweledge regarding current
density in material that is THINNER than the excepted skin depth,
knowledge of which is not required for a puny degree in English!
Unfortunately there ia a shadow on the screen that appears to be
readying himself for an attack on them there 'foreigners' that
are comfortable with impedance paths rather than using a ruler to
measure the shortest distance! I am sure that Alan will be able to
handle the shakespearian 'lip' that is about to come his way with no
problem at all.

The coax loop is a half wavlength phasing line. I don't recall the coax
type but I seem to remember that it was RG-6 (75 ohm) with F-connectors on
it. If you still have it, measure the outer diameter and compare it with
RG-6. The center conductor would have to be solid if it has F-connectors.
You're replacement would need to be exactly the same length...tip to tip.

I am moving my W-51 crankup from my old house to my new one. I will, of course, need a new base to bury in concrete and am planning to have one fabricated by a local shop. I haven't been quoted a final price on it, but I think it's going to run around $70-75 which I understand is considerably less than retail. If anyone else out there is also in need of one of these I could up the order. I am not in the business and don't have anything to gain out of this deal - just putting out a QST in case it can help anyone else out. The shop doing this has done other work for me - all excellent quality. They are in central Texas.

Thanks for your experience on that, Mark. I appreciate it. The details
you provided are exactly what I was looking for. At 6m length, it
should be quite manageable from a transport and setup perspective.
That 10m one you built sounds pretty interesting as well. Now that 10m
may go back to being like a vhf band for a while, I might give it a
try as well. Thanks Mark.
Happy Holidays to all!!

I would like a little bit to learn about how to receive as good as possible terrestrial TV signal (central Europe). I know a little about antennas, frequencies, channels, gain, noise ... There are many internet shops, which can sell me all I need, but I don't know well what I really need, to have my signal as good as possible. These are my typical layman questions: When amplifying signal from antenna - amplify only one channel or bunch of channels? , Amlify right away in antenna or when joining the signals?, How to join some channels together if they are close?, what can I do, if the signnal after joining is noisy ? etc ... I don't need to know detailed schemas of components - my understanding of electornics ended with tranzistor at school. Please do somebody know any internet addresses which can give me answers to my above questions? Thanks.

You have an amusing turn of words Rick. I got a chuckle out of it.

Are you saying that the FRAGO doesn't work?

Or could it possibly be that science is being done? Or are you saying that the 'Q' issue is just plain unimportant?

Say, you never took me up on the lunch offer--remember, I offered to have you down to the lab for lunch and a FRAGO (http://www.fractenna.com/FRAGO%20Brochure.pdf) demo-- so try this one on for size:

How would you like to critique the manuscript before it gets submitted?

Confidentiality before pub, of course, and need all comments back within two weeks. Submit date is after the APS deadline, looking at 20 January.

Let me know within a week. N1IR.com getting tweaked before launch and I don't want to be diverted given my small amount of time away from the lab.

Real busy; Busy. Busy. Busy.

Or do all I hear is a big fat--CLUCK?

I am confused. Where does it say that fractal antennas aren't applicable below 30 MHZ? Or does my 5th place in the 2000 10M contest provide a neat little counterexample?(To 'hams' Jerry, the 10M band falls from 28-29.7 MHz).

What is your motivation Jerry?Are we supposed to discuss COMPANIES here? If so, I can merely say that I am a well-versed designer of antennas from decametric to millimetric wavelengths.

Hope that helps and gives you a knowledge advantage:-)

Chip,
I see that you are once again under attack by the antenna group

These attacks have been going on now for several years with a few
breaks
while they turn and attack somebody else. What do you attribute these
series of attacks to? There is no doubt that Clerk has been an
effective Pied Piper in leading these attacks but why is he so
succesful in attracting such a following from otherwise intelligent
people? At times I attribute it to be against foreiners, other times I
feel it is because of the presentation of new ideas,
then there is the apparent love of debate where the best uses of
speech is valued more than truth, and then there is the current
thought on this side of the pond where it is 'You agree with us or you
are against us' !
So what is it that you think is the reason why so many can be rallied
against you with the onslaught of hate for so long ? You are certainly
not foreign born,
and the normal ham is interested in new antenna ideas, this leaves
only one thing in my mind, the love of debate , use of words to
discredit,the spread of misinformation and the discharge of hate from
relativly safe positions.
It is obvious that most on this newsgroup are fine people yet many
have the addiction of throwing sharp and heavy stones on a whim the
same as the
Pied Piper which seems so incomprehesible.

Best regards and I hope you had a great 'Harvest Festival' otherwise
known in this country as 'Thanksgiving'

3421. Ant Tuner Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-29 17:24:38 UTC
From: marvin rosen <raghead@worldnet.att.net>
Message-ID: <qpNF9.36333$hK4.3181045@bgtnsc05-news.ops.worldnet.att.net>
Source record: 130458

Is there any validity when using balanced feedline, to place
the balun at the input of the tuner?

Outgoing mail is certified Virus Free.
Checked by AVG anti-virus system (http://www.grisoft.com).

Hi Art,

My sense is that some people are so shocked that gurus would make themselves available, that they feel the need to stalk them. Some of these folks are out of work; some work for competitors; some have an antisocial sense of 'fun'; some just like to mix it up.

I have many friends here (such as yourself) and I enjoy you and their company. I have no problem ignoring the usual spectrum of bad taste and vituperative, and fortunately, I can afford to have others to assess when individuals cross over the line into defamation; IP piracy; and so on. I make it clear that I don't lead them there--but see no reason to give up my constitutional rights to communicate either.Certainly no one asked them to give up theres.Expression is not their problem, eh Art:-)?

I have absolutely no problem if someone concludes that I am litigious; difficult; and so on (ad nauseum). If that means that I have made efforts to resolve matters, which have not been remedied in others ways, then I fully understand why that speculation is applied.

Trust the fact that people are sincere and genuinely friendly when given half the chance, and ignore certain individuals' nonsense up to the point where a group of peers would conclude that there is something going on which goes far beyond a mere placement of silly insults.

Had a lovely turkey day; hope you did too!

73,
Chip N1IR

No Rick; its your perspective. Frankly it is not compatible with the history of the field.

The best always prevails; the issue is making sure the pioneers don't get shafted.

Incidentally, I noted with some interest that Napster now officially doesn't exist anymore; its (now modest) assets bought out for a penny on the dollar by Roxio.

This no doubt should send a shudder down the spine of pirates and those who feel that malicious expression (that is to say, statements which are demonstrably false) is now not free expression on the internet.

BTW, your response to my offer to let you review a manuscript on low Q, electrically small genetically optimized antennas is---

?

>
>--Rick

That indicates an absence of knowledge, not an inability to assess it. Let me enlighten.

Any optimization program allows for the opportunity to 'seed' the first pass with what's already known to work well. Hence to ask an FOM engine to assess what's best becomes very straight forward: it either continues to spit out what you start with, or saves the ones that are better.

Ed Altshuler had an interesting antenna produced by GA optimization(see Transactions APS March 2002) using a Cartesian gridded set of endpoints to constrain how to define the free parameters. That's a good starting candidate, as are others.

In all sincerity, if you have one to pass along then pass it along. Be easy to compare to others at this point. It hardly is an intractable approach.

Which is exactly what will happen at frequencies where the skin depth is
small compared to the wall thickness.

> Think about this carefully. In effect this path would have
> a significant impedance.

Which can easily be computed, and verified with fairly simple
measurements. This effect is often used for decoupling at UHF and
Microwave frequencies.

> There seems to be a misconception that the current cannot
> flow directly from the point of connection inside the tube
> to the outer surface.

The misconception is that high frequency AC current _can_ flow through a
bulk conductor whose thickness is large compared to the skin depth.

> Think about it this way. Take a long straight conductor
> carrying an r.f. current. Now disconnect it, make a small
> hole in a piece of copper sheet, slide it along the wire and

Ok.

> Now does the current flow up to the sheet, flow out over one
> side of the sheet, across the edge, back down the other side
> then continue along the wire,

Yes.

> or simply continue along the
> wire, through the disk and out the other side.

Nope.

> Why?

The question is 'why would it'? From your web page I see you are familiar with Whinnery. By far the best explanation I have ever seen is contained in the text "Fields and waves in Communication Electronics" by Whinnery, Van Duzer and Ramo.

Simply (and non quantitatively) put:

A circulating magnetic field always encircles a conduction current (Ampere's Law)
If a current is flowing through a conductor, than a magnetic field is also be present inside the conductor encircling the current.

A time varying magnetic field is associated with an electric field (Faraday's law).
If an AC current were flowing though a conductor, than a time varying electric field would coexist (and exchange energy) with the magnetic field.

Ohms law states that the electric field is zero within a perfect conductor, and very small inside a good conductor.

Since the electric field within a good conductor is negligible (you need to do some quantitative analysis in order to verify the validity of this statement), then so must be the magnetic field, and therefore the conduction current.

Another point of view is to look at the characteristics of electromagnetic wave propagation within a good conductor. The wavelength is equal to 2*pi * skindepth and the attenuation is 2*pi nepers per wavelength. Note the phase reversal at a depth of pi times the skin depth. Also note that even a thin copper sheet will be many wavelengths thick making it virtually impossible to predict the phase of the surface currents induced when what's left emerges through the other side.

A current traveling along the surface launches a wave into the conductor, perpendicular to the conductor surface. The wave is attenuated by 8.6 dB every skin depth and quickly vanishes.

Marvin, you need to define which 'input' you mean. Is the set-up TRX -> tuner -> balanced line > antenna? If so, is the tuner capable of true balanced feed on the antenna side? If the answer to this question is yes, then you don't need a balun. If the answer is no, which is more likely, then put a balun between the tuner and the balanced line.

3433. Problems With EDZ Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-29 19:38:49 UTC
From: "William M. Bickley" <bickley@dmv.com>
Message-ID: <uufgiathv5rm3a@corp.supernews.com>
Source record: 130372

I could use some help with this one:

Antenna is a new 88-foot extended double zepp, up about 35 feet. One end is in the clear. The other brushes the tops of a couple of pines before exiting on the other side of the treeline.

Feeder is 450 ohm window line, about 80 feet long, fed under the eave, thru a storage area, thru a wall, and directly to a Nye Viking tuner.

Neither the transceiver, amp or tuner are grounded to each other or anything else.

Performance is great (amazing, by my standards) on 80, 40 and 20 meters. At higher frequencies, I'm getting a terrible hum (or worse) in the rig speaker, the computer and the housewide audio system, to the point where the system is unusable, even at near-QRP power. No RF bite on the mike or any of the cabinets, though.

Removing the amp and adding a grounding strap from transceiver had no effect. Adding a W2DU choke between tuner and transceiver had no effect. Next step is to swap in a Johnson Matchbox, as soon as I can get it up to snuff.

This is my first entree with balanced feed, and I could use some advice and counsel.

TIA.

Bill W2ET

> range, have you?

Sure I have, but they have essentially the same problem as rotatable dipoles.
Antennas are scalable to any frequency but HF fractals and HF rotatable dipoles
have certain physical problems to solve that may stress their feasibility.
It is certainly easier to generate a von Koch snowflake curve on a PC board
for UHF than supporting it across your backyard for HF.

The center conductor (with insulation) was sticking out about 2 inches
beyond the braid. The glow was on the tip of that.

I have since switched from the 9913 cable loop tuning stub to RG-8. Much
better since more insulation around the center conductor. 9913 has a hollow
insulation vs RG-8 solid. No more problems. Loop works great!

Your extended double zepp is an extended double zepp on only *one*
frequency. Yours is designed for about 13.3 MHz. Is your ladder-line
at least six inches away from anything conductive including itself?
Is your physical layout conducive to balanced currents in the
ladder-line?

Exactly. As Bart points out, inside a good conductor the RF electric field and its associated magnetic field are both very nearly zero, and so therefore is the RF current (movement of electrons).

If you accept that the skin effect exists, then you're accepting that RF current flowing along a conductor will always push itself outward toward the surfaces. Having accepted that, it's inconsistent to *also* believe that RF current will dive radially through the thickness of the wall of the tube. It can't do both of those things.

Yes, an RF potential difference can exist between the inside and the outside surfaces of the tube. But each surface has its own separate skin effect, so there is no electric or magnetic field inside most of the thickness of the wall. No electric field = no current flow.

In other words, if the wall is continuous, and several skin depths thick at all frequencies involved, it behaves like an RF insulator between its inside and outside surfaces.

the field.<

Antennaland has a rich legacy of "innovators" with a perchant for rewriting Maxwell. Hasn't academic controversy always been important for preserving the integrity of the field?

>The best always prevails<

In this case, Best likely will.

>The issue is making sure the pioneers don't get shafted.<

Sometimes the issue is to ascertain if a self-proclaimed "pioneer" actually did anything worthy of the title.

Let's cut to the chase. Why not simply institute an "Apropraite Speech Code" here on the NG--just like a minority group over at Harvard Law School (in the People's Republic of Cambridge) is attempting to institute over there? With that luxury in hand, you'd be free to sue and destroy anyone who has the timerity to say anything that might make you feel uncomfortable or contradict your point of view. Come to think of it, hasn't fractenna been advocating that very thing for several years? By golly, you may be a pioneer after all!

>BTW, your response to my offer to let you review a manuscript on low Q, electrically small genetically optimized antennas is---<

When I had a wood stove-heated place in the OZARKS I had the SAME problem...

The answer is UP...I chose the highest tree nearby and used a slingsot to shoot some 30 lb monofilament thru the crown of the tree, and used it to pull some 16 guage insulated wire thru the tree to make a long wire antenna guyed with sufficient slack and springs to allow for flexing oif the tree in the wind.

For the TV I got a JFD Log Periodic Velocity antenna and a rotor and put it on the highest point on my roof...(satelllite was only a dream then)

Source record: 130382

Loop is square - 3.5 feet per side made from 1/2 inch copper pipe. Gamma feed. Tuning capacitor is the coax stub 6" to 24" depending upon freq and environment - estimates.

I do not have an analyzer so I am at a disadvantage. Go to A6CV's site and look for mag loops. There you will find lot's of info. I used a program called ANTENNA.EXE by KI6GD. It gives all of the need calcs.

I build the loop and stub as close as possible to calculated values. Then tune my receive looking for a general increase in background noise. I trim the coax stub until that noise area falls near the a ham band. Then I strip off the outer insulation for a length of about 2 inches. The by moving the braid along the center conductor insulation I "fine tune" to the ham band. From there I tune the braid for lowest SWR and at the same time tune the gamma match for lowest swr. 1:1 is possible with very narrow bandwidth on low bands and better on 10M. Efficiency proportional to size. Higher efficiency the higher the Q and the more narrow the bandwidth.

Hi Ed,

Corona is RF, not static.

Any attempt to provide a path to ground as a means to leak it, if
"successful," would inevitably be a poor RF solution.

Most corona problems I've heard of relate to its occurrence at the
corners of the loops (strange thing to say, corners). This generally
affects center driven loops - the solution is to move the drive to the
corner and the corona inducing high potentials are pushed 45ï¿½ to the
middle of the next wire which lacks that sharp bend to aid in corona
formation. The second, most obvious, solution would be to build a
loop without corners.

Hi Bill,

Are you running an amp off batteries? Somehow I think you would have
mentioned that so I will proceed on the assumption you are connected
to line power and have dismissed the implications of ground finding
its way to your rig.

Ground is there, you just haven't designed it to your needs and the
hum proves it. If you had 50 choices to ground, you would probably
hit the right one by 25. The choke was a good step, but it doesn't
match a solution to the symptoms you describe.

Your entertainment systems and your rig may share a common path
somewhere in the house. This is a conduction based RFI where levels
can be very low, and yet be more than sufficient to present the
symptoms you describe. The easier way to find the solution is to
break that unseen ground path (you were under the impression it wasn't
there anyway, so this will test that faith).

On the basis of this approach there are several easy tests. Is your
rig and any interfered with system on the same breaker? Throw it and
find out if necessary. If you lack access to the panel, there is
another way to determine. Pick one interfered with system and plug it
in by extension cord into a different outlet in another room or on
another floor. This will break the common path if these two shared
the same breaker.

Google.com has (almost) everything.
www.google.com/search?q=coaxial+cable+velocity+factor+174

0.66 (66% of 'c') seems to be fairly consistently quoted. That makes your 20' cable equal to 30' of vacuum, or air. I don't believe it matters if it is 1575 mHz or 1575 MHz or anywhere in between. Temperature might matter more than frequency.

'c' equals about 1ns per foot (air/vacuum).

Your cable is 30 feet equivalent of air, 30.8 nanoseconds (overly exact math), properly rounds to 31 nanoseconds since you wrote "20".

:. 31 nanoseconds.

Watch out for delays in the IN and OUT circuits. Lots more nanoseconds here and there.

If it is 1575 MHz, then it's a good thing it's only 20 feet or it might NEVER come out the other end... ;-)

Wait for confirmation from others. This is the Internet and nobody knows that you're a dog. Woof.

>
> Dick - W6CCD

The propagation velocity of RG-174/U, which has a polyethylene
dielectric, is 65.9% of the speed of light (often rounded to 66% in
data sheets).

20 feet = 6.1 meters

C = 2.9979 X 10^8 meters/second

6.1 /(2.9979 X 10^8 X .659) = 3.09 X 10^(-8)

Thus the delay in 20 feet would be 30.9 nanoseconds (which is
independent of frequency for the TEM mode).

Art, I assume that most everyone knows that rotatable dipoles below 14 MHz
are possible, just not very practical - same with beams - same with fractal
antennas. I'm not discouraging such. Mother Nature discourages such.

Wirebook III says the velocity factor is 0.66, same as RG-213.
It also says the matched line losses at that frequency will be
about 8 dB for 20 ft. of RG-174.

All solid polyethylene insulated cable, regardless of impedance, at HF has a propagation velocity of 66 percent of the velocity of light. You can work out the rest by yourself.

You can build, or buy, a cheap 2-meter antenna tuner. MFJ sells one,
and I think the early ARRL VHF handbooks might have had plans to
build one. A simple L network would do the job. While it won't improve
the antenna performance, it will provide a proper match to the transmitter.

Hi, Richard:

The amp, the transceiver and the computer (where I have the hum as well) are all running off the same circuit. I have the problem without using the amp at all, though.

I *think* the housewide audio is on a different circuit, but there's all kinds of coax running from it in the same storage room as the window wire. I guess there are multiple opportunities for trouble.

I will try the extension cord test to see if there is an improvement.

Now that I look, the window wire passes through the wall into my shack in an area which may be uncomfortably close to the 110 v. Romex running from receptacle to receptacle. I may try relocating the point of entry into the shack. I have not checked Cecil's question about how the window line is positioned versus itself, but will do so. That never crossed my mind. I guess I was expected too much of balanced line....

Bill W2ET

Oh, the shack is on the second floor, so grounding will be a challenge.

william
really what you have is a long flat top dipole
feed with LL some call it a G5RV
but...
a true EDZ is truely cut for one band
only .hince phased 5/8 wave with a
450 matching stub which is somewhere around 1/8 to 1/4 wave"guessing"
i dont have all my notes here
check out this site for a great
design engine for the EDZ
i have one each up for 75 meters and
40 / 20
beats a dipole or full loop anyday
for short skip in the 5 to 600 miles
range, good choice , but you need to get it right for it to play

Thanks everyone. 31 nanoseconds it is. I am installing a Trimble GPS disciplined clock which requires entering in the monitor program the propagation delay time for the feedline between the powered antenna and the receiver. With a 30 dB gain antenna, the Trimble can handle 20 dB loss in the feedline. 20-feet of RG-174/U calculates at about 7 dB. Right now the receiver is locked into the satellites and everything seems to be OK. The 1575 mHz frequency, BTW, is the downlink freq. of the Navistar satellites.

>Art

You are right in that skin effect is not some certain depth in a
shield at which point all current
stops. Current flows through the full thickness of a conductor or
shield. But it is highly
attenuated the deeper it goes. There are many skin depths in a
conductor, it is not just one
unless the conductor is very thin. One skin depth is defined as the
depth where the current has
dropped by 66%. The next skin depth will drop the current to 66% of
what was left and so on.
It does not take very many skin depths to highly attenuate the signal
to a value that is not
useable or even detectable.

Current on one side of a shield or tube can not get to the other side in any useable quantity
unless the material is extremely thin, meaning only a few skin depths thick. Richard has given the
thickness' involved at rf frequencies.

There are only two other ways that I know of that any current can get to the other side. One is
for the frequency to be reduced low enough so that the effective depth increases for each skin
depth. This has the same effect as reducing the thickness of the material.

The other way is if the resistance of the material over which the current flows is significant to see
a voltage drop in the conductor. This will produce a voltage and thus a current on the other side.

3466. Re: Ant Tuner Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-30 04:41:43 UTC
From: k9sqg@aol.com
Message-ID: <20021129234143.03974.00000127@mb-de.aol.com>
Source record: 130405

It depends on the impedance posed by the antenna on the bands of operation and the style of tuner. If you have a link coupled tuner, a balun is not needed. A double balanced tuner would need a choke balun betwen the tuner and the coax to the transciever. If you have a tuner that only handles coax, then a balun is needed between the open wire line and the tuner.

73s,

Evan

3469. Ferrite Core Choke Balun Alternative?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-30 12:58:21 UTC
From: Mark Hall <mark.hall34@verizon.net>
Message-ID: <NB2G9.15661$%r6.3717@nwrddc02.gnilink.net>
Source record: 130408

For a 5 Band Quad, I would need probably 50 ferrite cores to make ferrite choke baluns. Kinda expensive. The coax 6 turn trick on a 6" form is good, but rather cumbersome on a Quad. I've heard that loosely packing steel wool into a 2" x 12" PVC tube at the coax end works just as well, although big. Any comments on this? How about winding a coil (no idea how many turns) tightly around the coax jacket and shorting the turns? Maybe tuning the turns to the frequency of interest? It would seem that some configuration of "turns around the coax" would be equivalent to "coax turns". Any thoughts?

No that is not whining at all, it is a fact that innovation is
discouraged.
So I object to the continual harassment of Chip so now you want to hit
at me.
"Lord knows some very credible guidance was offered" That is true and
when you got it you trashed me since you feel I am an easy mark while
others say things
that are trash and you remain silent. If you and Roy want to be
credible policemen of what you consider to be the truth then you
should police ALL which includes Clark whose behavior is terrible. So
I inferred that rotatable dipoles
for below 14 MHZ is really no problem, surely you need something
better than that to intimidate me so that you can continue to harrass
Chip on his own ! The harassment by some to Chip just has to stop,it
has gone on long enough and is now being emulated by others with
others. I see that there is a thread on seven steps to improve ham
radio which is now of incredible length maybe you have a waiting
audience on which you can practice your skills. This newsgroup
consists of a wonderfull group of people who enjoy discussing ham
radio in a friendly way, lets keep it that way.

You have heard wrong. You can buy a balun kit from Palomar

http://www.palomar-engineers.com/Balun_Kits/balun_kits.html

for $13.50 (shipped) and be done with it. I've found ferrite sleeves
(same as the FB-56 that I believe Palomar uses in their balun kit) at
swap meets for $0.25 each. I use 12 of these on a piece of RG-142 for
a balun on my 40-80 meter dipole.

You might stumble into something that works on one band but you have a
5 band antenna remember.

[snip]

OK, I believe most of us here support you Art, and your often thought provoking
ideas, and most here even seem cut you a lot more slack than you deserve in respect
of "peer review", considering some of your assertions.

So STOP WHINING it won't make you any friends and it only detracts from your
otherwise excellent efforts here. Take criticism like a man with the rest of us, "if you
can't run with the big dogs then stay on the porch."

Art, YOU are welcome here anytime. BUT please STOP harrasing and defaming the
three "R's" - Roy, Rick & Reg three of the most selfless and foremost contributors of
time, knowledge and effort to this, one of the best, USENET technical newsgroups.

That said... your protestations as to the treatment of Chip are an entirely different matter.

Why you deign to protect a pontification, booring Ivy League, Ph.D. with the most
crass commercial intentions to USE this NG for selfish purposes, I'll never understand.

Heh, heh... Chip certainly does not need Art Unwin to protect him from stupidity!

Despite his overbearing manner, I believe most would cut Chip at least some slack
if he were to follow normal conventions of NG ettiquite. In other words, if Chip stopped
the crass commercialism and crude promotion of his company and its'

products, and if
he quit, attempts to intimidate others with advanced degrees of questionable
applicability,
condescending Ivy League tone and manner, impotent threats of litigation,
poses with
silly "patent pending" postings, and attacks on innocent passersby, rather
than dealing
with pure scientific methods, why then he might actually be accorded some
"respect".

My personal experience with Chip here on this NG, began a few years ago the
very first
time I encountered his postings. I was one of those innocent passersby, in
search of
technical information. I posted a simple straightforward question to him
about
fractal antennas, and "wham" out of the blue, he "trashed" me personally,
questioned
my motives and made fun of my question, and this was on the very first reply
to my
posting. And... I had never heard of him or fractal antennas before that
first encounter.
I was just interested to learn more! It so happens that I am a long time
developer
and user of mathematical optimization theory, techniques, and programs
applied
to several areas of electro-technology. I had just never applied those
techniques to
antennas. And so it seemed to me that although the "new pseudo-science" of
fractal electromagnetics may have been something I was unfamiliar with, I
certainly
was familiar with mathematical optimization. Would this not entitle me to
ask
Chip some innocent questions about his optimization methods? Why not I
thought.

What a creep! Since then I have made it my business to learn more about
fractal
antennas and the so-called new science of "fractal electro-magnetics".

And guess what... it turns out that "so-called fractal electro-magnetic
theory" is no more
than one of an infiinte number of methods of "linear loading". Many of
which are superior
to the fractal methods. And so with such unabashed promotion by Chip, one
may be
excused for considering his brash claims to be almost akin to those other
occasional
"theories" promulgated by opportunistic cream skimmers who attempt to gouge
the
uninformed, and whose patent applications used to be consigned to the

dustbin
by the patent examiners along with with the perpetual motion machine
patents!

Stop questioning Chip you say, heh, heh...Poor Mr. Chip, jull of bluff and
bluster
and overly defensive about a technology for which his outrageous claims of
optimality
are at best extremely marginal.

Art what the heck do you want from the NG? You won't get any slack here by
standing
up for charlatans, opportunists and self-promoters.

Meanwhile continue to make your own contributions and take the questions and
criticism
in the manner in which they are intended. Or... "stay on the porch".

What?

So the less material thickness provided the lesser the antennuation !
Is that correct?
If that were true would not efficiency increase as thickness decreases
as long
as overall resistance (area is increased)in not reduced ? That sounds
to good to be true even tho I use very thin aluminum foil as a
conductor and get good results.

There are many skin depths in a
> conductor, it is not just one

snip>

This raises an important question, if there are 'many skin depths' it
suggests
that when the material is 'very thin' the formula for skin depths goes
out the window. I must be misunderstanding something here,can you
point to where
I misinterpreted what you said.

Hi Art--

>No that is not whining at all, it is a fact that innovation is discouraged.<

Kinda reminds me of the "Invented Spelling" debate. I doubt anyone has a problem with someone "getting it wrong" in the course of exploring something new for the first time. What I have a problem with is watching someone persist in a poor or wrongful assumption, resist all counsel, and defend their positon with conjured-up science despite credible evidence to the contrary. I don't call that "discouraging innovation" or trashing anyone, I call it education.

Recall discussions held here on critical coupling, controlled fields, CFAs, parasitics caused by photons, and many other quirky topics--none having anything to do with Chip. All having everything to do with the proliferation of flawed science.

BTW, far from being a "technocop", I've never claimed to be the brightest bulb in the technological chandelier--and its not at all unusual for me to get pulled up short for something I've written or said in conversation. But, I don't let that stop me from doing interesting things. Moreover, when Tom, Roy, Steve, (or several others from the pool of excellent resources who frequent this group) point something out, I usually pay attention. Why? Because they're usually right--and becuase I'd rather learn something useful than waste time defending something stupid.

>So I object to the continual harassment of Chip...<

So noted--as I object to the endless parade of threats.

INNOVATION: Introducing changes and new things.

INABILITY: Lacking the means and skills to do things correctly.

The two concepts should never be confused-- especially when the latter is often easy to correct.

>> attenuated the deeper it goes.
>
>So the less material thickness provided the lesser the antennuation !
>Is that correct?

Forgive me, Art, but I don't think the penny has dropped. Let's try a slightly different way of saying the same thing...

For a conductor with a skin depth D at a certain frequency:

63.2% of the total current flows in the outermost layer, from the surface down to depth D. The other 36.8% flows at deeper depths.

86.5% of the total current flows in the layer between the surface and depth 2D. The other 13.5% flows at deeper depths.

95.0% of the total current flows in the layer between the surface and depth 3D. The other 5.0% flows at deeper depths.

98.2% of the total current flows in the layer between the surface and depth 4D. The other 1.8% flows at deeper depths.

Jumping to say 10 skin depths, 99.995% of the current is accounted for. Only 0.005% of the current flows at deeper depths.

Even deeper inside, the current is still there at some calculable level - it never goes exactly to zero, but it's negligible for any purpose (except perhaps when calculating shielding effectiveness at low frequencies or for extremely thin shields).

> if there are 'many skin depths' it
>suggests
>that when the material is 'very thin' the formula for skin depths goes
>out the window.

If the material is only 3 skin depths thick (or 6 if current flows on both sides) then the error in the calculated RF resistance is only 5% - and that's hardly "out the window".

The RF resistance for any arbitrary thin cross-section - comparable with the skin depth, or even less - can be worked out *exactly* with a bit of extra math to allow for the boundary conditions... but it's an intellectual exercise of no practical relevance to amateur radio at HF or above.

> I use very thin aluminum foil as a
>conductor and get good results.
>
Even if you could find foil that's almost as thin as the skin depth, the increased surface area (compared with any practical antenna wire) will more than compensate.

3482. Three Phase Antenna Feedlines

Newsgroup: rec.radio.amateur.antenna
Date: 2002-11-30 18:29:52 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <asb030$63q$1@sparta.btinternet.com>
Source record: 130322

For more than 100 years advantage has been taken of the fact that 3-phase transmission lines, for the same weight of copper and support, have a significantly lower energy loss than 2-wire lines. Those seeking the ultimate in DX performance at any price should consider what changes will be needed around their antenna farms.

Home-brewing a 3-phase choke-balun is an obvious and easy task. But a 4:1 transformer requires much thought.

A centre-fed horizontal dipole would have to be replaced by a centre-fed horizontal tripole. Vertical and loop antennas would need corresponding modifications.

There will be a race between Japanese and US manufacturers to design and produce the first 3-phase 100-watt, all-HF band transceiver. But no doubt there are a few dark-horses coming up fast. Could be a radio amateur will be first at the winning post.

Much depends on development of an entirely new range of antenna tuners. Just an empty black box? The SWR meter's death knoll is already sounding. The age of the TLI is here.

Revolutionary new computer programs will be needed to predict wierd and wonderful radiation patterns. Has the isotrope been attainable all along?

rewriting
> Maxwell.

==========

They are in good company. Oliver Heaviside was the first of the innovators.
In the field of radio all the others followed on from HIM.

The only thing I associate Maxwell with is an inductance bridge to which his name became attached and which I made great use of in connection with transmission lines, although I understand he was a great man in fields other than electric fluids.

Hear! Hear!

|Art:

|OK, I believe most of us here support you Art, and your often thought
|provoking
|ideas, and most here even seem cut you a lot more slack than you deserve in
|respect
|of "peer review", considering some of your assertions.
|
|So STOP WHINING it won't make you any friends and it only detracts from your
|otherwise excellent efforts here. Take criticism like a man with the rest
|of us, "if you
|can't run with the big dogs then stay on the porch."
|
|Art, YOU are welcome here anytime. BUT please STOP harrasing and defaming
|the
|three "R's" - Roy, Rick & Reg three of the most selfless and foremost
|contributors of
|time, knowledge and effort to this, one of the best, USENET technical
|newsgroups.
|
|That said... your protestations as to the treatment of Chip are an entirely
|different matter.
|
|Why you deign to protect a pontification, booring Ivy League, Ph.D. with the
|most
|crass commercial intentions to USE this NG for selfish purposes, I'll never
|understand.
|
|Heh, heh... Chip certainly does not need Art Unwin to protect him from
|stupidity!
|
|Despite his overbearing manner, I believe most would cut Chip at least some
|slack
|if he were to follow normal conventions of NG ettiquite. In other words, if
|Chip stopped
|the crass commercialism and crude promotion of his company and its'
|products, and if
|he quit, attempts to intimidate others with advanced degrees of questionable
|applicability,
|condescending Ivy League tone and manner, impotent threats of litigation,

|poses with
|silly "patent pending" postings, and attacks on innocent passersby, rather
|than dealing
|with pure scientific methods, why then he might actually be accorded some
|"respect".
|
|My personal experience with Chip here on this NG, began a few years ago the
|very first
|time I encountered his postings. I was one of those innocent passersby, in
|search of
|technical information. I posted a simple straightforward question to him
|about
|fractal antennas, and "wham" out of the blue, he "trashed" me personally,
|questioned
|my motives and made fun of my question, and this was on the very first reply
|to my
|posting. And... I had never heard of him or fractal antennas before that
|first encounter.
|I was just interested to learn more! It so happens that I am a long time
|developer
|and user of mathematical optimization theory, techniques, and programs
|applied
|to several areas of electro-technology. I had just never applied those
|techniques to
|antennas. And so it seemed to me that although the "new pseudo-science" of
|fractal electromagnetics may have been something I was unfamiliar with, I
|certainly
|was familiar with mathematical optimization. Would this not entitle me to
|ask
|Chip some innocent questions about his optimization methods? Why not I
|thought.
|
|What a creep! Since then I have made it my business to learn more about
|fractal
|antennas and the so-called new science of "fractal electro-magnetics".
|
|And guess what... it turns out that "so-called fractal electro-magnetic
|theory" is no more
|than one of an infiinte number of methods of "linear loading". Many of
|which are superior
|to the fractal methods. And so with such unabashed promotion by Chip, one
|may be
|excused for considering his brash claims to be almost akin to those other
|occasional
|"theories" promulgated by opportunistic cream skimmers who attempt to gouge
|the
|uninformed, and whose patent applications used to be consigned to the
|dustbin
|by the patent examiners along with with the perpetual motion machine
|patents!

|
|Stop questioning Chip you say, heh, heh...Poor Mr. Chip, jull of bluff and
|bluster
|and overly defensive about a technology for which his outrageous claims of
|optimality
|are at best extremely marginal.
|
|Art what the heck do you want from the NG? You won't get any slack here by
|standing
|up for charlatans, opportunists and self-promoters.
|
|Meanwhile continue to make your own contributions and take the questions and
|criticism
|in the manner in which they are intended. Or... "stay on the porch".
|
|What?

So you object Roy. Then where the hell were you on that thread which
doubled in length after your comment ? Where were you when the
Australian had a disagreament with you that upset your idea of being
infalliable so you refused to respond. Some say if one does not
respond it is a sign of aquiescence,I don't agree with that
wholehartedly but you DID walk away. You did a similar thing with me
on my antenna idea,after blasting in succession the E/H antenna,
the contrawound antenna, the fractal antenna work a new manufacturers
antenna (two element phased)you took my work as an easy mark to hit
as did another person which led Clerk to attack me with abandon .
Well after lots of harassment even he has had to backdown on the
validity
of the antenna and you were supplying private modelling work in the
background for him.
Now after accepting my claim as valid he then took off after my claim
of gain
(collinear) gain which stopped the subject from going away where you
were wrong by acting hastily after your successes with other peoples
claims. Now the attacks by your friend Clark continue again with the
allegation that I stole an idea from its true inventor(I am too much
of a dummy to come up with a good idea) fortunately I had patented it
years ago, now you talk of apologies.
Well Roy eventually somebody is going to make these antennas in the
future
and you will be seen as not infallable all the time tho I would
suggest that you are correct most of the time. You supplied a
modelling program on my antenna

to Clerk where upon he turn around and agreed with my claim, did that work
provide proof of your prior statements or was it a embarrisment to your position
True I did not debate the antenna ideas in the smartest way and I firmly believe I should have done better in responding to those who inquired with an open mind when I was thinking the worst. Now I am getting disparaging remarks from another for asking for change with respect to one of your enemies, this guy lives close to Chip and has made no secret of his glee of the changes in Chips employment, and you want apologies from me. Well Roy my antennas do work as I say regardless of your putdowns and those of your surrogate,yes they are my ideas and the old patents proved it and some day the harassment of which you were part of may well come out to embarrase you where you assumed that these ideas was nothing more than the trail of claims that you have taken upon yourself to attack. Roy I take no pleasure in exposing your incorrectness especially when you have helped so many but this derisiveness regarding my antennas has gone on to long, especially since they work as I say. If you feel that you are acting on behalf of the truth (you stated earlier something like that 'you will always attack false claims' then you should do that even handedly without reference to 'comedy' and without special deference to a follower
such as Clerk.

But wouldn't you need a phasing network at the antenna to put the
signals back in phase? Or maybe a beam with three driven elements?

Here is what Roy actually said:

"If the connection is to the inner surface, the shortest path to the
outer surface is along the inside to the nearest opening, then out.
This might be a short path or it might be long. If the path is long,
it'll add substantial inductance and, in the case of a small loop,
unnecessary loss."

So speaking of respect, I suggest that you offer Roy your apology,
Art.

Sorry, can't help you there.I know fractal antennas gained a lot of
interest in the past few years but I was not one of them as I was busy
on other things.
I was refering to use of dipoles below 14 MHz of which I am a firm
believer.
Someone brought into the subject 'loaded' dipoles from somewhere which
is fine also,no complaints. There are many people that have yards that
are too small to accomodate large antennas that many brag about but
they are equal in my eyes.

But Reg, unless you somehow rephased those three phases, they wouldn't radiate.
A dipole re-phases the ladder-line's phasing with two 90 degree turns. How
many turns at what angles would three phases require?

I think maybe one of the reasons the fractal idea and its promoter catch such a razzing is because there is nothing out there that people can try for themselves. Its like saying I've got the best so-snd-so but I'm not going to let you see it.

What do you think, Art?

Stop being so paranoid. Nothing has been orchestrated. The only "problem" here is that someone outside the fractal community has placed your work and the work of others in the fractal field, under a fine microscope and questioned your hypothesis on the significance of fractal geometry. Unfortunately, the only way you know how to deal with this is to cry foul and make claims of some great conspiracy.

Had you and the others approached this issue scientifically and even bothered to compare antennas with fractal geometries to antennas having the same physical properties and only differing in geometry, you wouldn't be in this situation.

I would have to agree. I have both methods of receiving MW. IE: large
wire antennas, and a tuned loop. I'd have to go with the loop any day.
On MW, using an overly large wire antenna is fine, except that you
pretty much have overkill as far as signal input, and the signals come
a blasting from every direction.
Not really desirable as far as picking out certain stations where
there is likely to be interference. My round 16 loop is much better at
weeding these stations out of the muck. Much better for nulling out
local noise also. And the loop without a preamp still gives plenty of
signal. Another plus to the loop is reduced sideband splatter from
adjacent stations, as the loop is quite hi-Q. The audio is generally
cleaner. Also less prone to picking up static crashes. A beverage is
nice, but I don't have that kind of room. I tried my loop out in my
truck on an old delco AM-FM I use. Worked very well, and very hi-Q.
You had to retune just moving a small amount. But was a very hot setup
for MW if you can live without a digi display. Here in the house, I
usually use my 706mk2g on MW. MK

Hi Bill,

Simply visit:
http://www.qsl.net/kb7qhc/antenna/fractal/index.htm
The bulk of my work is pedestrian, lock step, monotonous and exact.
It in no stretch of the imagination comes close to "practical," so
scan the pages and results. I closely examine a couple dozen fractal
models to illuminate their advantages and shortfalls.

You might even visit one page in particular:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm
which, if you read the URL closely reveals one proposed "practical"
design and my simpler alternative. This design reveals one of the
amusing traits of fractals specsmanship, but I will leave that for you
to discover. :-)

Practical is quoted to denote the self-irony implicit in its
association with things fractal.

I have far more than the 300+ pages the top link leads to, so if you
find any interest merely ask (every antenna published at the same link
has an EZNEC file available for immediate download, or ask me because
I lost some DIY's from links to other pages I've written). I would
caution that most of this "practical" design requires a considerable
investment in maintaining a complex geometry. For my DIY's, I
typically design a wire antenna supported by a fan of guide ropes -

but there a picture is worth a thousand words.

Being a vertical, it doesn't really matter. It could be a foot above
the beam and be ok. MK

Hi Jerry,

I won't duplicate my response to Bill here, except to repeat one link:
http://www.qsl.net/kb7qhc/antenna/fractal/index.htm
for reference.

As offered to Bill, if you see anything interesting, but it remains
intimidating (not unusual for most folks - these are complex
monsters), ask me to stretch it to your band if you wish.

Hi Ian,

You can't find foil that thin. It has to come supported on a milar
film - the type used to shield computer cables and RF transmission
lines. ;-)

Cecil, I said the dipole would be replaced with a TRI-pole.

A TRI-pole consists of three horizontal 1/2-wave wires spaced at 120
degrees. The three phases would be fed directly from the three line wires.

I've only just invented the thing! Can't test one till some kind person
loans me a 3-phase 2m transmitter. 3-core appliance power cable will
suffice for the feedline.

My first thought was that the system would radiate perfectly
omni-directional in the horizontal plane with a nice vertical null similar
to but even better than a turnstyle.

But I havn't thought very hard about it.

Should one of us think again ?

Any independent opinions?

What does Terman say ?

I guess the radiation resistance between each phase is around 50 ohms. Who
needs Eznec?

The less attenuation to the other side of the conductor, assuming the
conductor is a shield or
tube, in which case you do NOT want the current to go to the other
side.

With a wire as a conductor, as you reduce the size of the wire the
current will flow closer to the
center than it did with the larger wire but as you go to a smaller
wire you loose surface area that
is all important in rf. The net result is loss in conduction area as
the skin depth is so small. Most
all significant conduction takes place so close to the surface.

>There are many skin depths in a
>> conductor, it is not just one

>point to where
>I misinterpreted what you said.

No the formula does not "go out the window". It is still the same. The
skin effect is exponential,
just like the discharge curve that a capacitor and resistor gives. It
is called one skin depth when
the current has dropped about 2/3 of full value. It does not mean that
there is no more. It is just
a means of measuring it.
See Richard Harrisons post that gives some examples of how thin the
material is to be
considered "one skin depth" at various frequencies.

If you had a piece of material that was only one skin depth thick then
approximately 1/3 of the
current would reach the other side.

Ian has summed it up nicely as to how the current decays as depth
increases.

BINGO! Depending on the actual fact of the matter, this is a classic
Ground Loop scenario. The object and the solution is to break the
loop.

>

>guess I was expected too much of balanced line....

Don't give up yet. Your problems, as described, have nothing to do
with balanced or unbalanced lines (nor shielding, nor proximity).

However, as a counter-test to that assertion:
1. Place rig into a controlled, interfering mode;
2. Move rig output to dummy load;
report difference in symptoms here.

>
>Bill W2ET
>

Hi Bill,

If any extension cord test will work, it will have to work from the
rig's plug, not the interfered system - it is much to complex, as you
describe, to decouple. You may ultimately have to find an outlet that
has a dedicated breaker to prove this.

Another alternative is to extend to an outlet on the same breaker, but one that is closer to the breaker. You are then throwing the line loss into the extension, which is isolated and whose potential (at the rig's floating ground) cannot be injected into the interfered system.

Normally, the huge cross-connections of grounds would not be a problem with your usual household electronics. This is simply a convenient circumstance of luck, not design.

It's sad that this is the best you can do for an apology for publicly attributing to me a statement I didn't make.

I don't answer a lot of your postings because frankly, I can't understand what you're trying to say. Those that I do understand are often devoid of any technical information that I can comment on. And I have no interest in engaging in the sort of pissing contest your most recent posting exemplifies. You've had your say, to which you're entitled. It contains adequate information for readers to decide for themselves whether it represents an accurate description of my character and motives, without a response in kind.

And I certainly don't respond to every posting, even every one directed toward me. To do so would be to drag threads out interminably after everything relevant has been said. A time comes in every discussion where the reader has to decide for himself what to believe, based on what's been said. My choice of when to quit posting and when not to quit might not suit you, but then I learned long ago that I can't please everyone.

I'm frankly tired of defending skin effect. There's ample information available for anyone who can read, in countless volumes published during the past century. The principles are as well established as Ohm's law, and I certainly don't feel it should be necessary in a forum like this to have to defend Ohm's law. For those who eschew books, there's a great deal of accurate (and almost certainly inaccurate, so be careful) information available on the web. And there have been many, many postings and explanations here on this newsgroup, easily accessible from http://www.groups.google.com. Anyone too lazy to learn how to avail himself of these resources and put a modicum of thought into the matter isn't worth the time and effort to continually respond to.

Hi Cecil,

Synchros and Servos have been resolving three-phase fields into a
simple, single resultant vector for centuries.

It's still nothing more than phase.

Ahhh... The Maxwell Bridge, excellent! I've used it myself in the
"modernized"
Op-Amp version.

Back in the 19th Century every electro-scientist worth his salt had a
"bridge"
named after him.

Ever used a "Brooklyn Bridge"? How about a London Bridge?

I always wondered who VSWR was, and why she got a bridge named after
herself.!

Sorry to burst your balloon Reg, But many years ago Hydro quebec went from three phase transmission to DC on their 750 Kv lines from Churchill falls on James bay to southern Quebec.More than 1000 miles. More efficient and less loss. Maybe you can model that for your antenna feed lines. Check it out on their history of their James Bay Hydro development program. Keith, VE3JKC, ex VE2ANC.

Hm, that would work for us, too. The trick is to dangle your transmitter
at the feed point, and send it B+ via a DC "transmission line". If you
took as much care with your insulators as Hydro Quebec does, it'd be
sho' 'nuff efficient, too, all right. I'll leave the technical details
to the reader.

Roy Lewallen, W7EL

Just a thought - as Cecil says it's the Devil who makes me do it, perhaps
3-phase fractal antennas are worthy of investigation.

I understand radio propagation in cluttered environments, as with mobile
phones, rotation of polarisation at the transmitter improves reception
reliability. Spirally rotated waves in both directions, available with
3-phase transmitters, may offer even greater reliability.

Fractenna, any comments?

Wes I have apologised many times to people to avoid a fight but all it does
is bring more derrision
Roy used the term 'shortest path' which is 'distance' and I referred to that particular word in reference to the 'shortest path'
It was not a long question by me...All I said was what has 'distance' got to do with it? His response was he didn't understand!!!!!!
For crying out loud it couldn't have been that hard to see
the words 'shortest path' which means shortest distance in his own post! I referred to it again referencing 'hangups' with the word 'distance' where reference to impedance path would be more apropriate as the thread got longer but again he did not respond.
Then he did the same to Fowler who then started another 'follow up' thread in an attempt to get a response to which Clerk joined in as is customery. I have no problem with the vast majority of Roy's responses or even his idea about going after antenna untruthswhen he feels like it,but he is not infallable, and the fact that I as a nobody would question what he said doesn't justify his disdain.
I respect the man for his terrific knoweledge but as an individual I am beginning to have questions
since he worked with Clerk in degrading both my work and integrity.

Wes, your advice is probably good and I would do it in a second to cut this bickering out. But I have done it before and the contempt continues
as if winning a debate is more important than the truth,
that I am whineing because I disagree with a guru when I am only a nothing,
not a name or a guru..
I may not be the greatest in defending my integrity but I have seen what has happened to others so I am not going to hide,I am not going away regardles how many times I am hit, I will fight back and stay in the ring until rendered unconcious so that they who attack me will have cause to think again when they choose another prey.
Best regards to you Wes, and thanks for taking the time to post even tho I reject the suggestion. I consider you as part of the vast majority on this newsgroup who are both polite and respectful even tho I may many times suggested the rediculous and I very much appreciate that as most are terrific people.
What I say about my past experiments are the truth. I am not lying !. (I did notice yesterday Clark belittle the old 13 element experiment I did in a snide sort of way again) The claims for my antennas are true. I also did not steal the idea of capacitive coupling as stated

which my old patent should should have dismissed. Despite what Clerk
said yesterday about one of my questions ,I follow the aproach of not
asking just one expert but asking many experts, of which there are not
enough of if I got involved in some threads. Can't we all move on and
stop attacking Chip? What ever he did or didn't do I believe he has
suffered enough. Maybe by doing that this malaise that some have in
America that if you don't agree with me then you are against me, will
cease and we can get back to antennas rather than people, foreigners
and winning debates.
Happy weekend to EVERYBODY.

Heh, heh... Reg... Now you'r talkin. I'll bet those beachside armadillos
will respect my old Belgian made
FN 9mm pistol... but my dear wife has thrown out all my 9mm ammo. She
worries that I might go "postal",
after finishing off the radial grubbing armadillos. She worries,
unecessarily, that I might carry on to the local
coral snakes, the alligators, men-o-war, sharks, and other such denizens of
the beachside. The worst are
the two foot long "palmetto bugs" who want to come onto the patio for a bite
of steak while it's still on
the grill. I am always amazed by the number of "mean critters" we have here
on the Florida barrier islands.

Hi Bill,

Now we are getting somewhere. Did you in fact determine that it was interfering before switching to the Dummy Load? Just firing up in a problematic band is not enough.

But, in all confidence of your ability, it would seem this is not a conductive RFI, such as I described with moving plugs around.

Given this positive result, you can now examine those things that have drawn your suspicion, such as proximity. If you can rummage up another transmission line that you can run through another path (so you can do A/B testing) you might be able to touch upon the answer.

This may be difficult, but attempt to fire up the line with it terminated by a Dummy Load (but only if you have a 4:1 balun to use in the transition to the Load).

Another way to determine the state of your transmission line is to measure the currents in each leg to see how much imbalance has been cast into your antenna system (for that is the apparent problem from this new test's results). This is probably not something you are prepared to do, by lacking RF current meters.

You can rig up your own if you have any meter, and a hell box full of components (find a toroid; signal diode: 1N914 style or better; a cap; a resistor). Knowing you have an unbalance (also called Common Mode) does not bring a solution, but it does allow you to see how much of the problem improves, remains, or becomes worse as you experiment.

This will confirm any issues of proximity and shielding, but this may easily be a simple antenna geometry problem (your system is beneath one leg of a low element - solution is the inverse of the problem).

> and that's hardly "out the window".
Now we are getting to the nitty gritty, it is suggested that skin
depths are an exact science and I question this.
If I use a material for low frequencies that is as thin or thinner
than a stated 'SKIN DEPTH' then there must be a change in thinking.
If we are to agree (and I think we do) then there must be a large
change in the so called skin depth after all the material started off
at the same thicknes!
Since the current does not get thru which I have personally confirmed
in experiments, then there has to be a increase in current flow per
unit depth . Where can I be wrong with this (you can be blunt)?
If I am correct then what is the effect on actual radiation, something
for nothing? The change in skin depth for this thin material must be
quite drastic, more so than a minuit correction factor as stated
with use of a formula. Let me be more simplistic, thickness of
material
0.001 inches, stated skin depth for the stated use 0.001 inches
Formula states this depth takes care of 60% of current flow (actually
less
because the current does not penetrate fully.
So what conclusions can we come to 1 the skin depth must have
changed radically i.e. denser current flow at the surface 2 current
energy changes form ie heat

Exactly...this again suggests a radical change in skin depth
is happening. I am not saying that others are incorrect in their
stance,
just that I see skin depths as being emperical rather than absolute
mathmatically derived because of the admittance of a 'correction

factor'.
If I wasn't actually using a thin metal shell as a radiator then this sort of stuff would not come up but then what would you expect from someone such as I?
Thanks for having another shot of overcoming my understanding abilities.

Hey Rich, that started me thinking. Do these Fractennas lend themselves well to parasitic operation? For that matter do magnetic loops? Are they that different? How about a Fractal Magnetic Loop parasitic element antenna? Maybe I should check your website first to see what's there. When I asked Fracky a few years ago about some specificics so I could make up one to try he got all huffy and insisted the information was all on his website. If it was it was *very* well hidden from view.

Dick

3538. Re: Skin effect - a follow up.

Source record: 130277

Skin effect is an exact science, and only one quantity is called the "skin depth" for a given homogeneous material. The skin depth is easy to calculate, and the formula can be found in a great many references. But it's easy to misunderstand what it means. If a conductor is many skin depths thick, the current density decays exponentially from the surface, and the current density at any given depth is easily calculated. The skin depth is the exponent of the exponential factor in the equation relating current density to depth. At one skin depth, the current is 1/e (e^-1) ~ 37% of the density at the surface. At two skin depths, the current is e^-2 times the surface density, and so forth. An interesting and fortuitous mathematical oddity is that the effective resistance of a conductor many skin depths thick happens to be exactly the same as if the current density were constant with depth and equal to the surface density, but abruptly stopped at one skin depth. This makes RF resistance calculations easy, but although it gives the correct results, it isn't a representation of what's really happening.

The point I think Art is trying to pursue is: What if the conductor isn't at least several skin depths thick? The answer is that the current still decreases with depth, but not at the same rate as it does when the conductor is thicker. The calculation can still be done, but it's no longer one you can punch out on your calculator. The calculation involves using Kelvin functions, which are related to complex Bessel functions. I'm quite sure the general problem can't be solved in closed form, but requires numerical methods. Given the required computing capability, however, the current at any depth and at the surfaces can be computed just as surely as it can with thicker conductors. Incidentally, calculation for non-homogeneous materials (e.g., plated wire) also requires numerical methods unless each layer is at least several skin depths thick.

Skin depths are very shallow for good conductors at HF or even MF and above (and decrease with increasing frequency), so the assumption that the material is at least several skin depths thick is usually a good one when dealing with RF.

Considering how simple the calculation is, I'm sure that Art and anyone else interested in this topic have done the skin depth calculation for materials of interest. Art, you're interested in aluminum foil. How many skin depths thick is the foil you're using at the frequencies at which you're using it? If it's at least 3 skin depths thick or so (where the current has decayed to about 5% of the surface density), calculation using the common assumption of exponentially decreasing current should be adequate for most uses. If it's shallower than this, then the more difficult numerical methods should be used if you require an accurate

answer.

Hi Dick,

In all probability it is as hidden at my site, but more a matter of
not seeing the forrest for the trees.

Do they lend themselves to parasitic operation: no more better or worse than many shortened and loaded.

There are only two relationships that matter for fractal benefits
1. You seek something small and resonant;
2. You seek something large and wideband.
Small being less than quarterwave, and large meaning more than 1 wavelength (often two).

My pages go volumes in just these two characteristics examination against frequency and form (over iteration).

Results are in, no one at the other end will appreciate your effort.

However, I do include a few loops. I will browse their address a little later for you.

I'm not a power engineer but I'll waffle on for a bit.

The trouble with trans-continental AC power lines is phase shift and a tendency to develop standing waves. There are problems with synchronising widely spaced generating stations specially under fault conditions. And believe it or not, at power frequencies there are significant losses due to skin effect in the conductors. A small increase in diameter to reduce such loss increases weight, wind and ice loading, and the cost of everything. I wouldn't be surprised if these days aluminium over high-tensile steel is the favourite.

Despite losses in the AC-DC and the DC-AC converters the lower cost of constructing and maintaining single wire power lines shifts the balance. The cost of electricity generation in different parts of a continent affect choice of transmission system. If it's cheap nobody minds if some of it is lost. Coal, oil, hydro-electric, tidal, atomic.

Another economic factor is construction and maintenance of ground electrodes. Buried radial systems get warm and gradually dry out. So soil resistance increases. Or they suffer from electrolytic corrosion. Undersea (salt water) DC cables allow low resistance submerged earth plates. But fish are not very happy. Differences in age and performance of generating plant also affect economics. Things change with plant lifetime.

An important consideration is the potential difference between the ground electrodes at each end of the route. This is caused by rotation of the earth and tidal flows in the seas and oceans across the the Earth's magnetic field. On trans-Atlantic phone cables, where submerged bi-directional amplifiers are powered by constant current DC power supplies from each end, the potential difference between N.America and W.Europe can rise to several thousand volts at the peaks of solar-caused magnetic storms. Amplifier power supplies allow for a maximum difference of 10 KV. It was one of the old-timers (Wheatstone, or was it Faraday?) who first noticed and measured the voltage induced in a wire under the river Thames. It varied with the tidal flow of the water.

Before connecting your hand-held multi-range meter to the inner conductor of a 3000-mile coaxial cable with the aid of a crocodile (English) clip, it is advisable to use the insulated shorting-rod thoughtfully provided.

There are many DC power transmission systems in various parts of the globe. Around 1955 I first found formulae for calculating the resistance of various ground electrode systems for given ground conductivity in a Russian article describing a trans-Siberian DC power route from a hydro-electric power station across the Urals into populated areas. The ideas are incorporated in a few of my programs having been amended to give sufficiently accurate

estimates of ground loss at RF.

For a number of years there has been a power cable (25 miles?) under the English Channel. Presumably it is used to equalise peak generator loads between the UK and W.Europe at different times of the day. No need for synchronisation of rotating machines. French electricity must be cheaper than ours - 90 percent of the French stuff is atomic and the rest is hydro-electric or tidal. Or thereabouts.

If anyone should ask what's the DC resistance between two places on the Earth's surface more than a mile apart - it's zero. Everthing is contained in the ground electrodes plus crocodile clips.

Hi Bill. I don't know if we have communicated before but I recognise
the underlinninmg theme. I did not and have not hidden anything. I
subjected myself to the withering interogation by Clerk and gave
figures and facts the best I could even though I considered the method
to be objectionable and I was not privy to that which Roy was
supplying him. At one time he even admitted Iwas correct in my claim
and then went on with the attacks. I also supplied a page
in a attempt to clarify.Others brought to the attention of the group
patent
numbers that describe what I say. The same goes for capacitive
coupling where the allegation was that I stole it from the real

inventor and where I had described in detail how it works and why it works. I can't see how you can
suggest that I am making claims that others cannot prove for themselves.
If I misread your post then I apologise for my response

Also, peak voltage is a limiting factor. The DC voltage can obviously be
set just below the limit and thus carry more average power than AC.

Years before fiber was invented, for short periods, I worked alongside AT&T engineers in cable manufacturing plant. So I know what you mean. Their design rules were brief and simple. And let's admit it - they worked well enough. ;o)

But I suspect the staff did not obtain the same job satisfaction as I did.

Try looking in the phone book for a real hardware store, a boat or RV
supply store, a farm supply store, or a tool store.

Last time I looked at them in Harbor Freight (a tool store; they may
be on line), they ran from about $20 to about $60 depending on how
heavy duty you wanted.

Hi Jack,

I'm currently using a hand-crank winch designed for a boat trailer that
I picked up from the local marina. All different kinds of sizes available.
I'm using one on a 40 foot crank-up tubular mast with pretty good results.

Hope this helps
Tom

Hi Art,
I didn't mean to put you on the defensive which I obviously did, I was simply looking for an "Idiot's Guide To Build A Fractal Antenna". 300 pages of theorems haven't guided me the basic dimensions nor have a bunch of wild-ass claims and an opportune photo of a Senator with Martini toothpick in hand visiting the Fractal Lab.
I think if there was any substance to any of the claims, pro or con, then some regular schmuck user like me could say "I tried it and it sucks/was the best antenna ever".
I don't see that in this case and I think thats a basic failure on the part of 'inventors' that think snow-balling an interest is more important than actual users on-the-air experience.
At least the EH antenna is publicized. I have found some tin foil and 4" PVC, all I lack is a basement to see if the antenna performs equally outdoors.

Hi Dick,

The url
http://www.qsl.net/kb7qhc/antenna/fractal/Square%20Gasket/index.htm
goes to a page illustrating three variations of a loop of one form.
The first section of the page introduces a single iteration square
gasket and sets-up the baseline. The middle section of the page then
introduces a variation in iteration (which reduces the outer perimeter
of the loop) and notes the change in resonances. The 200 Ohm
resonances of the first iteration are nearly identical to the 50 Ohm
resonances of the second iteration.

Because each design consumes the same amount of wire to build the
pattern, the second iteration has useful resonances in a smaller
bounded area. I should also note that this logic also extends to the
first iteration resonating in a correspondingly smaller bounded area
as the conventional full wave loop antenna.

Now, as this is all first resonance stuff, by and large, and that is
most often with wavelength proportions of less than a halfwave
overall, the nature of radiation imposes a certain bland sameness to
most radiators that reside in this domain - these fractals in no way
break the mold of convention.

Hi Dick,

http://www.qsl.net/kb7qhc/antenna/fractal/Triangle%20Gasket/index.htm
reveals a design that borders on the tedious for the sake of
warshipping a false god. It is a fractal design by spec and
definition, and yet it has no particular quality other than it is
probably one of the more "practical" forms to construct.

I would call this a staged loop matching of a regular structure with
interlaced tuned stubs.

Consistent with my method, I vary one thing, the placement of the
drive point on this web, across three major hierarchal points. The
resonances of the antenna are very affected by such choice. I have no
idea why I ranged the frequency from 5 to 300 MHz - I must've been
bored with the results usually limited to a top frequency of 30MHz.

I've put a lot of miles on the odometer with these suckers, the three
choices for drive points selected was an educated guess at finding the
greatest variation in range for all possible connections; you may, of
course, consider this jaded editorialization and build your own to
mine the possibilities.

Boring does not mean lossy by any means. And a fractal antenna is
NEVER worse than a standard antenna in standard situations (ï¿½1dB).

Kel-Tec's are nice... but just because they are light, ya don't have to go
overboard.

Heh, heh, Rick I know you live in the land of "Live Free or Die", where in
the winter
you can "hide" anything under those LL Bean winter parkas ya'll use up there
in the New Hampshire hills, and so "hiding" those Kel-Tec's would not be a
problem for all y'all Yankees.

But you gotta feel sorry for us Rebels here in FL... since even though a
non-felon
can get a "concealed carry" permit here in Brevard County, all anyone can
wear most of the time around here are T-shirt, shorts, and flip-flops,
now...

I ask where can you hide 6 - 7 Kel-Tecs in your surfing wear?

>DEPTH' then there must be a change in thinking. If we are to agree (and
>I think we do) then there must be a large change in the so called skin
>depth after all the material started off at the same thicknes!

This is correct.

But you are wrong to say that "skin depth is an inexact science". The science is very exact. The situation when cross-sections become very small is totally understood.

The problem is with language. The only reliably correct language of science is mathematics. Any other spoken or written language is an approximation, and occasionally falls down.

The term "skin depth" is always used to mean an inherent physical property of the material. It is calculated exactly from two other inherent material properties, resistivity and permeability (although it also varies with frequency). Used in this sense, "skin depth" is independent of the actual physical dimensions of the conductor.

If you read Roy's most recent posting, that is exactly how he uses the term; and that is perfectly correct, because that's how the community of engineers and scientists has agreed to use those two words.

Thus you may hear such statements as "This gold plating isn't as thick as the skin depth." This makes perfect sense because "skin depth" is being used in its understood meaning: one of the inherent material properties of gold.

Hi there people, I am new to the hobby, just recently (3 days) got my license and am now looking to homebrew my own antennas. I suppose that's what makes this hobby so interesting and enjoyable, I love a good challenge.

I am looking for information on how to build both a 70Cm and 2 M beam antenna. Looking for good proven performers, not looking at conducting EME, but would love to be able to make some nice simplex QSO's over a fair distance.

I have heard of Quagi antennas for 70Cm, are these worth building over a normal driven element type beam, or am I best to start with the basics?

Which leads me to the next question, what's better a gamma style match or a folded dipole DE? and lastly, what's considered better, through the boom, or shielded from the boom?

If someone can point me in the right direction, or if anyone has plans please drop me a message at vk2hxy at hotmail dot com.

Warmest regards from an Aussie Amateur

Source record: 130304

Hi,

I'm looking to organise a club project to build a folded dipole for the UK 70MHz band- that aim is to get some newly qualified Intermediate / Novice Licences onto 70MHz.by converting a bit of PMR kit and building an antenna.

Basically, I'd like to 'copy' a commercial antenna, I have which covers 68 to 88MHz or so.

However, I can't figure out what the balan and impedance matching arrangements are- they are 'potted' in epoxy or similar.

Someone has suggested that it would use an "inverse balun" comprising a 'hair pin' of insulated wire would on a metal former. The loop is connected to the feed points of the folded dipole with the coax (50 ohm) inner to one of the dipole feed points but the braid to the metal former.

I've never come across anything like this before but I am told Jaybeam used to use this method.

Can anyone cast any light on this please- I've found nothing on the web. I always thought that a balun was bi-directional.

Source record: 130305

Mark,

I am using a compromised version of your description. My 5-bander is fed with three feedlines: 10/12, 15/17, and 20. A single run of RG/8 leaves the shack to a top-of-tower mounted switchbox. I placed 8 ferrite cores on the RG/8 just prior to the switchbox - for a shotgun approach covering every band - and then exit the switchbox with quarter wave RG/6 matching stubs for each band combination. Works great... good SWR curves and at least 1.2:1 resonance on every band.

The quad now tunes better than the previous design - which had 3 untuned RG/8 stubs from the switchbox, each of the 3 stubs with its own set of cores. The SWR curves of that design did not have 1.1:1 resonant points - on some bands the best I could get was 1.6:1 (with resulting SWRs well over beyond 2.0:1 on the band edges).

I finished this new design in October and some of the resonant points are not where I want them... but that fine-tuning will have to wait until next year's warm weather. My re-design goal was for lower than 2.0:1 SWR across all 5 bands from 20 - 10, and I have achieved that with the exception of the top end of 10 meters.

I have an Excel spreadsheet that plots SWR if you are interested...

Actually, it appears to be beyond the ability of a standard ham 2M
antenna tuner. When properly calibrated (which I didn't do before),
my MFJ-924 is only able to dial in an SWR of 3.0 for the marine band.
The same antenna give SWR=1.2 for 2M without correction and 1.1 with
correction.

Exactly, not to mention that I feel like my fly is open and I have spinach stuck between my teeth. So, in real life, I don't carry anythng but a pocket knife (just to set the record straight).

>Kel-Tec's are nice... but just because they are light, ya don't have to go overboard.<

I like the P-32 because if you have to get rid of one in a hurry, you can chew it up and swallow it.

>Heh, heh, Rick I know you live in the land of "Live Free or Die"...<

Odd that it's the safest place to live in the US--what with all those guns in the hands of its citizens!

Dear Peter:
Not much of a problem. Look at this page:
http://www.kel-tec.com/prod02.htm
and you will see why a P-32 can disappear in shorts or even on a chain
under a shirt.
This topic is much more interesting!

Hi Larry:

Yeah I'm debating the 1/4 WL matching sections. EI7BA started with them, then took them out. W/O the matching sections his SWR went down significantly. It's a crap shoot I guess. Haven't seen much RG-11 75 ohm cable around at Ham Fests. Putting the ferrite cores at the input to the switch box would save a bunch of cores. I have a 4 el spider quad so it will be complicated no matter what I do. He added 30 and 40 meters to boot. The 40 meter being a dipole folded around the spreaders. I'm thinking I might be able to get a 2 element 40M on there somehow. Better crank up the Autek on this one. Does your switchbox ground the unused elements?

Jack,

I was able to pick up a winch for my Wilson TT45 tubular tower at a boat shop that is identical to the original. I think it was intended for use with a boat trailer. Price was in the 15-20 range. Same place also has stainless steel hardware.

This is an interesting engineering economics issue. Factors include the cost of wire, the cost of insulators, the cost of converting DC to AC so that transformers may be used at the receiving end, the distance between generation and use, and (to a minor extent) the cost of generation. The comparison usually assumes that the line will be run with the same peak voltage, which is equal to the average voltage when using DC. Thus, at first glance, the use of DC allows more power to be conveyed. Use of an even number of conductors is preferred.
The Russians have used DC transmission lines in a setting similar to the Quebec setting. Some islands are supplied from the mainland by DC.

Mac:

Thanks.

Yes, I know all about Kel Tec it's located in Cocoa, FL about 10 miles North of my place here in Indialantic, FL.
They have a target range there where prospective customers can try out their products.

The P32 is a very "cryptic" and convenient weapon for personal concealed carry use.

I read last week where the airline pilots in the US will be allowed to carry pistols in the cabin starting next year.
This new program might prove to be a windfall for Kel Tec. With the proper training and understanding of the
safe use of handguns, I believe that arming flight deck personnel in airline cockpits will be another useful element
in the new overall approach to improving the airline industry's security against terrorists and others who don't care
about the safety of innocent airline passengers. Hindsight is always 20:20, and it is too late now, but I believe that
if it had been well known publicly that members of airline flight deck crews may be carrying concealed
firearms the fate of at least some of the doomed Sept. 11 flights might have been different.

Incidently, or co-incidently, both Cocoa, FL the Kel Tec factory site, and Indialantic where I live are located on
the wonderful "Space Coast" a few miles South of Cape Canaveral here in beautiful Brevard County, FL which
issues concealed carry permits to "qualified" citizens who request such a permit.

Mark,

Yes, unused elements are grounded (it's a TopTen Devices 6 position switch).

I bought 100 feet of RG/11 from Cable Experts, and used it for 1/4 wave stubs on 40 and 30 meter delta loops, and for the three stubs on the quad.

I also experimented with EI7BA's 40 and 30 meter antennas on the quad, but could not get them to behave properly and removed them.

You will definitely want an antenna analyzer of some sort for this work - I use an MFJ 259B.

I remember a time when taking an engineering exam I was given for some
reason
the electrical engineers paper. I barely made it and all the other
mechanicals failed.This firmly implanted into my mind the superiority
of the electricals in mathematics. This lesson has come home again and
tho I am slow in comprehending
the time spent by the guru's has not been wasted on me, tho it was
probably all understood by others.I thank all for the considerable
time in explaining to me
the intricacies of skin behavior where my understanding has shot up
immensely
(No, not 100%)and as Peter has pointed out all people that gave me
extra licence
to pursue this line of questioning. It is hard to stay in a horrible
mood when people are so generous with their time
Thanks
Art KB9MZ......XG

Ok,OK,OK
For you and you alone I will accept that I portray a good example of
inability. I am guilty of not accepting that any antennas that
I talk about are trash and cannot possibly work. Yes, I am also guilty
of portraying others ideas as my own and thus am guilty of stealing
and worse still, of lying. I am also guilty of trying to defend what
I call the underdog. I also will not add XG to my signature to this
particular post so that pain is not laid on those in the U.K.
I will go out to the porch for a couple of hours as Peter suggested
and hopefully somebody out there will take the time to bring out a cup
of tea and biscuits. During this time I will cogitate on the
indignation
that I have of being guilty of all these things and when I fight back
I am labelled a whiner, which really hurts.
So Rick you have got all what you are asking for, the idea of sharing
things is incorrect as it leads to old wives tales . Ofcourse I have
no idea of my demeanor when I return from the porch tonight as it is
mighty cold here in the Midwest and my sugar levels are now going out
of sight
despight the extra needling Hic, that I am getting.

>The P32 is a very "cryptic" and convenient weapon for personal concealed carry use.<

Install a miniature Laserlite sight under the recoil-spring guide, slip a couple extra magazines into the little zip-up carry case, and it makes a neat package. Polymer body comes in a variety of colors for the fashion-conscious.

Hi OM,

Depends on where your contact is, and what band.

For Line-of-sight contacts a couple of hundred foot hill is like a
couple of hundred foot tall tower. You can ground mount your antenna,
as long as obstructions do not block its "view." The radio horizon
would be roughly 20 miles away, or 40 miles to the furthest, similar
hill with ground mounted antenna (equally clear of obstructions).

If you are working over the horizon (far over), you can think of the
hill as having less earth to soak up your signal before it gets on its
way. Being on a ridge or a peak would probably bring some advantage
in the form of a height multiplier: 1.18 for Pikes Peak on 80M; 1.22
for Machu Piccu below 40M. 1.005 for Mt. Rushmore at 160M; and so on.

Start by grounding the transceiver and the tuner. This should improve your reception and transmission, the hum may also vanish. I've used a 4 foot copper plated rod and number 6 copper wire, even though the best rf ground is 8 ft of copper rod.

3587. Stealth or Balcony antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-01 19:24:26 UTC
From: Beans <beans@gate.net>
Message-ID: <3DEA61EA.89EACBB5@gate.net>
Source record: 130226

I made an antenna yesterday morning that would seem to be a good one for anyone needing a stealthy antenna or one for an apartment balcony. What I did was take a ninefoot piece of 1 inch pvc pipe. I have two 20' lengths of copper wire wound around it, center fed with a balun. One length of wire goes up from the balun, the other down. they are attached to the pvc with lock-ties. The whole thing is mounted vertically, just standing up.I have it mounted 1 inch (yes-inch) off the ground. No wire touches the ground. It loads up with an antenna tuner.

Granted, it's not the best antenna ever, but it is very stealthy, and is very compact. I guess it is similar to a Force-12 Sigma. It would be easy to put this on a balcony. I have it in a coutyard. From Florida I have worked California, South America, and Europe this weekend, so it does get out. 20, 15 and 17 all worked well.

This was extremely easy to assemble..took about 5 minutes, but I had the pvc.

Jeeze. Shoot somebody with a .32 and you're just going to make them grumpy. Better stick to shooting coral snakes.

Which reminds me. I'm way out in the desert and one day when I came home from work I found a rattlesnake coiled up on the doorstep. Since my wife often greated me at the door, I started shouting at her to not open it until I could find my square shovel (my weapon of choice) and dispatch the snake.

She opened the door anyway and burst out laughing at my distress. It seems that she found the snake near the door earlier in the day and dispatched it with one shot from the pellet rifle (right between the eyes) and then put it on the door mat for me to find.

Dear Group,

I will be putting up a beam at my new QTH shortly. Before I moved, for a number of years I used a TH6-DXX at 55 ft. and was satisfied with its performance. I am trying to decide if I should go with a new TH7-DXX, which would be very similar to my old beam, or one of the Cushcraft X7 beams, which I know very little about. Either antenna will again be installed at 55 ft. Any opinions on which one you would go with?
Thanks and 73

I have 2 TALL vertical stick antennas mounted on the roof of my vehicle. They are body mount types with excellent grounding of both the antenna and the rigs. One antenna is for 10M the other is for 2M. The mounts are about 2 feet apart. These antennas are @7-8 feet tall. The problem is that when both antennas are up the swr's are very high on both. When I remove either one of the antennas the swr's a relatively flat for the rig and antenna that are still up. I think the antennas are reacting with each other but why and how? But most importantly how can I get the swr's down and have both antenna in place at the same time. I do not want to spend a lot of money buying many different antennas to see how they react with each other. Since the holes are already drilled in the roof of my vehicle re mounting the farther apart is not an option. CAN I HAVE MORE THAN 1 ANTENNA MOUNTED TO THE ROOF OF MY VEHICLE AND HAVE ACCEPTABLE SWR'S?

Please help me

Hi Nuff,

Here we are in December (not August, September, October, nor November)
and how many self-imposed deadlines not met? No science can explain
that except Psychology (not really a science is it - or were you
thinking Astrology?).

The Statue of Imitations is perfectly obvious as most would call these
variations of a single design a one-note opera.

Nuff appears to be short on results and apparently in need of a new
bulb for a flaky crystal ball. Luckily there is always some
troglodyte in the background willing to give it a rap to see if that
can stir up the snow.

As for the admission
>>> 'fractals do no better than other small/broadband/frequency
>>>independent/antennas'.
>>>

>>>The answer is 'yes'.
That only took, what, seven years to confirm from similar observations of many correspondents here over that same period? Sense is beginning to prevail in that regard to only be replaced by a new wife's tale of optimization which already has taken more time to NOT accomplish less (current score of zero) than Steve's six examples done of an afternoon's doodling. More than two years "should" allow enough time, don't you think?

I would offer that frango keep its day job; but I keep mixing up cognitive process with simple candidate hi-grading. Now that fractals have been wholeheartedly abandoned, there is scant artifice available to provide a mantle of respectability.

As I recall, the rule of thumb for spacing antennas is 1/2-wave at the
higher frequency. That would mean a minimum spacing between them of
38". It would help if you could describe the antennas in more detail.
Are they commercial types? Do they feed below the roof?

Balderdash-- in rural locations, moving your antenna as little as 1/4
wavelength will take a signal from MINIMUM to MAXIMUM ! why? because of
different wave fronts caused by propagation cause the various recieved
signals to ADD, or CANCEL the recieved signal. in fact, if you are going
down a road , listening to your radio , at night, you can MEASUER THE
WAVELENGTH (reciprical of the frequency) between the NULLS in the signals
(1/2 wavelength points)!! go for the most antenna you can get, but doel
(or more feeds itno the pattern would help the most! jim nn7k

3605. Re: G5RV antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-02 01:39:59 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <asedle$79a$1@helle.btinternet.com>
Source record: 130244

Hi Kevin,

The G5RV is so simple a plan is not needed. But should you obtain plans there are several versions.

The only common factors are the electrical length in wavelengths of the 'top' and the electrical length of the feedline. Zo and velocity factor of the feedline, although quite critical, are very vague. It was originally designed in the days when the vogue was to couple the PA tuned tank to an open-wire feedline via a link winding over the tank. But read on:

Just erect a dipole which is 1.5 wavelengths long, end-to-end, at 14.15 MHz. The physical length is approx 102 feet.

Centre-feed it with a 450-ohm ladder line which is 1/2-wave length long at 14.15 MHz. The physical length of 450-ohm feedline will be approx 31 feet depending on the line's velocity factor.

That's a G5RV.

Some people connect a length of 75-ohm or 50-ohm coax between the transmitter and balanced feedline. Whatever you do, unless you operate only on the 20m band you will need a tuner. And you may even need one on THAT.

The G5RV is modelled as a special case of program DIPOLE3. But as you will see the G5RV plus coax, on bands other than 20m, performs worse than a random length antenna with a random length feedline of random impedance without any coax. It doesn't need a computer program to deduce that fact. The coax got there when the link coupling disappeared and the disadvantage of an exact half-wavelength of open wire feeder became important in modern residential accommodation. I don't think G5RV was ever short of real estate in which to erect antennas.

With all HF multi-band dipoles of this type a tuner is needed. Fit a 1:1 choke balun between the 450-ohm line and the tuner. An open wire, 600-ohm line has even lower loss especially if you can bring it right to the shack as G5RV intended.

Incidentally G5RV didn't use an SWR meter to tune up.

To predict what to expect and see the effects of modifications, download program DIPOLE3 in a few seconds from website below and run immediately.

It will estimate efficiency of any dipole, at any height, with any combination of any two feedlines in tandem, of any impedance and of any length. It also calculates the L and C values of an L-network tuner which will always work.

Balun ratio is allowed for if used. All answers available in a second or
two. No training course necessary. Can be used by numerically-minded CB-ers
and professionals. ;o)

3606. Wire antennas for HF (new and clueless about antennas!)

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-02 01:53:34 UTC
From: "Jackie L." <buzzygirl@REMOVE.attbi.com>
Message-ID: <y2zG9.202677$QZ.29900@sccrnsc02>
Source record: 130245

Hello,

I'm new to the hobby (was licensed 10/02) and am in the process of learning CW so I can get a General upgrade within the next 6-8 weeks. I have not bought an HF rig yet, but I'm thinking about the IC 718, which looks to be nice and easy for a beginner to use, I don't need lotsa bells 'n whistles myself. I'll buy a separate VHF/UHF rig for local work, and already know what antenna I'm getting for that rig.

The issue I'm having is this... I've done a thorough search of the environs around my house, and have come to the conclusion that the only type of antenna I will be able to use will be a longwire type for HF. Why?

Well... my place abuts a park to the south, I mean just 10 feet off my deck, there's park property- ergo, lots of trees. There is no room on my roof for a beam or vertical either as a result of overhanging trees (I don't own the house, the owner won't let me put up an antenna there anyway). A dipole coming off a tree won't work, because I've got kids that play in the yard, and they will for sure run into it where it'll be coming into the house-high-traffic play area. The only other spot I could put up a vertical would be too close to powerlines. I have no attic to speak of other than a puny crawlspace (I live in a rambler). So.

Here's my question- if I were to buy a long-wire type antenna and snake it along the roofline or gutters, and bought an automatic antenna tuner, could I possibly get enough signal push and pull to make it worthwhile? I don't know much about antennas, and the stuff in the ARRL antenna book I borrowed from a friend is going right over my head now (no pun intended- I do intend to learn more about this subject, but right now, that book's too advanced for me).

I have no CC&R's or other restrictions to deal with, other than living in a heavily treed-and-powerlined area. Also, any suggestions on good websites on antennas for absolute newbies to build would be most welcomed.

If I have to buy some smallish antenna for indoors, I'll do so, but I think I could make a longwire work in my situation. Unless there is some miraculous, low-profile HF wonder-antenna that I'm not aware of, that I could strap onto a gutter bracket or onto the house, just outside the window, that would pull in signals from far away? I am looking at an eave that is sitting about 6 feet from my head out the window; it would be so easy to attach something along the edge of the roofline, or even drape it off the gutters or whatever, as the connection would come right into the area where I will have my shack, with no danger of anyone running into it from outside or touching it without a ladder (the house is built on a slight incline as well). But being an utter novice in antenna theory, I don't know

if that would work, or if the gutters would interfere, or what.

Thanks in advance for your suggestions. I'm sure you get questions like this all the time, but I'm really new and I know many hams like to help out the newbies.

Message-ID: <aseeotbrs1@venus.btinternet.com>
Source record: 130246

There are probably two carbon blocks separated by a thin layer of glue or paint.

The paint breaks down at crudely 500 volts which provides protection for internal phone equipment against voltages above 500. Very good for protecting phones from lightning strikes near phone lines. Been used for 100 years ?

But 500 volts is too high for radio receivers.

Source record: 130247

Dear Ed:
A few observations:
1. 70 feet high will significantly improve 20 meter performance.
2. Consider a log periodic array. The T10 described here works very
well on all bands 20+
http://www.tennadyne.com/default.htm
LP do not use traps.
3. The X7 only covers three bands. There is a lot of action on the
other bands. Cushcraft service has been seen as lacking
4. The TH7 only covers three bands. It seems to be favored over the
X7. The new MFJ Hy-Gain service remains to be seen.
5. All of the above antennas have a purchase cost that is about the
same.

73 Mac N8TT
P.S. If you do go for a T10, ask me for hints on its assembly.

Hello Reg

Some of the newer protectors are three-terminal gas arrestors. It might
do for a long wire on a tube receiver, but they will probably fire on
moderate TX power.

Hmmm.. those trees sound real interesting.. the long wire will work, but you'll need a real good earth ground close to your tuner. You can use small wire for low power (like 20 Gauge which is hard to see from 20'), and just snake it through the trees using whatever branches it lands on. #20 should survive as long as not too much tension is used, and it doesn't get wrapped around branches. I use a sling shot to launch a small fishing weight tied to a spool of fishing line. Hold the spool with a cut off coat hanger planted into the ground. Let the fishing line pay off the end of the spool. Pull the wire up over the branches, and shoot another for the next branch. At the end of the wire, hang a weight so it will give with the wind. You'll get better results if you can get something like a G5RV multiband wire antenna up. Earth ground won't be critical, and there's a good chance you won't need a tuner on at least some bands. Maybe install it as an inverted V, sloped on the side. use a tree to pull up the center, then plant the two ends out far/high enough so the kids won't run into it. G5RV's available in Kit form on E-Bay for like $30, depending on the length and lowest band covered. I wouldn't mess with verticals (too much effort with earth ground/radials). Good news is you have trees which make great sky hooks! Good luck!

Well, I didn't really understand what you were describing with the fishing line and slingshots (I am *really, seriously* clueless about this whole process) but the problem here is that the trees that I *could* use for any sort of tree-strung wire antenna- i.e., those closest to my shack- are too close to power lines. I would not attempt to climb or slingshot anything into them for that reason. Most of the trees just outside where my ham shack will be snake their tops through power lines, unfortunately... I should've posted that to begin with.

Not necessarily, as some of the newer "gas" protectors fire around 2-300 volts, and are self clearing- in fact, these appear to be what are being inserted into their screw in protectors (same diameter, length, ect) , used by Alpha-Delta , in their antenna protectors, and rated to 100 watts, and to 1- kw (keep in mind, at 50 ohm, lots of amps, but not much voltage, depending on the gas insert being used in these! but, wouldnt try this with the old carbon protectors (not paint protected, by the way, in fact repaired by the phone co, by scraping off the "dark" carbon, to the color of the rest of the block), and the older carbon protectors actually had a "gap" between the carbon block, and the ceramic piece that held an embedded piece of carbon in its middle! --jim nn7k

Okayyy... Radio Shack sells a push-up 36' guyed metal mast for about $70. Find a clear spot, hoist it, guy it. The mast will hold up the middle of a dipole. The ends of the dipole can droop down in a "V" pattern. This is called an "inverted V" dipole.

Look in that antenna book you borrowed, and read up on "inverted V dipoles".

Possibility?

Ahhh.. well power lines would be a problem. If those trees are off limits, you could try loading into the gutters on your house with a tuner. To eliminate the requirement for a good earth ground, you might be able to figure out some way to connect the gutters on house together and feed them as a loop with your tuner. I've had excellent results with horizontal loop antennas at low heights. I'd recommend the loop, but I've been called "Loopy" more than a few times. Good Luck!

What do you mean by "feed them as a loop"? How does one do that?

I would consider SteppIR.

Covers all frequencies from 14-54 MHz.
Very lightweight.
Optimized at all freqs...bandwidth not a factor.
Only 3 elements...much less objectionable appearance.
User reports have been awesome on user group.
Better performance than LPDA at fraction of the size.
No traps, resonators, etc.
Instantly reversible.

You can check out the reviews at www.eham.net/reviews. I installed a Cushcraft X7 about 2 months ago and I am extremely satisfied with it's performance. It's installed at 50 feet. It can even be used in 12M and 17M with a tuner.

I know nothing of the TH7-DXX.

Actually, if things keep up like they are, I'll have to apologize to Cecil. We're not having a dry winter here (in Oregon, not Washington, but that's o.k. -- we get along ok with our brothers to the north), but nearly a Texas-dry winter. Why, I could have used ladder line for a couple of weeks in a row.

Cecil, if you ever get tired of plinkin' at armadillos with your arsenal, or runnin' 'em down with your monster truck, come on up to Ory-gun. We could use some weather forecasters with your skill. Any non-felon can get a concealed gun permit here in Oregon, and your truck would be right in place in any of the rural areas (provided it's properly tricked out with a populated gun rack and NRA sticker). Your shootout-winner will pass as a 10 kW CB whip, no prob. So, except for the rain, you should feel right at home.

I don't really get your point. Are you talking about reducing fading?
If I had that much room, I would use beverages, but I don't have room
for beverages. And if I ran a beverage, I doubt I would want to place
it as high as I could get it.
5-10 ft off the ground is plenty. You are talking 470 ft of wire for a
1/2 wave just at 1000 kc.
Nearly 1000 ft for a full wave beverage. And then it needs to be in a
straight line to function properly. I have a funny feeling this may a
be problem in the mountains. Then you have the problem of being stuck
in that one pattern unless you run more beverages. If you run just a
fairly long random wire that possibly will have bends, etc, I would
consider it fairly omnidirectional.
In that case, I can't see how it would be better than a loop as far as
overly receiving quality. I have an inv L for 160m, and also a T
vertical for the same band. Also a dipole. All are fairly "hot"
antennas as far as MW, but I rarely prefer them over the loop. I have
no way to null crud out. And you would have no way to do this using
wire antennas, unless you had multiple beverages, or whatever. I kind
of doubt he is going to want to go to that much trouble just to listen
to a few MW stations. I can't see the point of worrying about wave
fronts and propagation in this case. They will constantly vary
according to many factors. You might want to clarify on this.
I don't see how he would be able to null out unwanted stations and
noise using a single wire. Using a loop, nulling a local noise source
or unwanted signal is usually very sharp and critical on the placement
of the loop. How are you going to do this kind of precise nulling
using wire antennas that don't require an act of congress to install?
I find it much easier to turn a small loop that sits on the floor next
to me. And the loop is dirt cheap to build also. Another plus... MK

That's right, connect them together (but provide a open circuit feed point for your tuner) making a conductive loop around your house. Do a web search on "horizontal loop antenna" or something like that. You probably won't be able to get a full wavelength on 40 meters (~135') unless you have a very large house, but with a tuner it should work on 40 - 10 meters. If you have aluminum siding this idea probably won't work at all. It's worth a try for an unobtrusive/dirt cheap antenna.

Thus you are not motivated by issues of science and innovation. Say Art; isn't it funny that when I offer to show these guys hardware or to critique results they just kinda fall into insults and gun discussions?

Or better yet, they pretend that I didn't spend a huge number of hours from 1994-2001 educating hams on fractal antennas.

There is a war going on fellas, and I see no reason to provide project information to hams at this point. Sorry, but that's how it is.

If you get info from elsewhere, ask yourself who its coming from and why its being provided.

I require a public retraction of this statement. You have asserted that I have not approached fractal antennas scientifically.

This is demonstrably false.

Your statements indicate that you do not consider our disagreements as scientific ones between colleagues, and that some other dynamic applies. That is not acceptable to me. I am giving you the opportunity to correct this here,

where the statement was made, and return the issues to ones of science between scientists.

Cordially,
Nathan Cohen

Again, the issues are scientific fact --as it applies to showing your statements are demonstrably false--and secondly the statute of limitations in relevant jurisdictions. Ask a lawyer what that means.

Your statements here are a false presentation of the value of fractals (which is not an issue relating to me) and false statements regarding me and my work.

The rest is for you to contemplate in your copious free time.

Cordially,

Nathan Cohen

3633. Re: Wire antennas for HF (new and clueless about antennas!)

Source record: 130172

Jackie,

Yours is another case which defies conventional wisdom, ie "higher is always better" and others which we won't bother with now. What you need is something workable that is also practical and do-able in your situation. Lots of us have been there and might be able to help by recounting some of our experiences.

I've found that the best simple, easiest fed antenna is a simple single band dipole. In your case I recommend you try to use 40 meters if you can find about 66 feet of space to hang it. It won't need to be straight, it can bend in whatever ways needed to fit. Tho higher IS almost always better, low will work very well and a low mounting height is not as much a signal killer as other factors, such as close proximity to other metal things which can soak up RF and detune it causing matching and other problems. Always get the feedpoint up as much as you easily can, that's the high current point on a dipole and means the most toward radiating your RF. The height of the dipole ends is not so important. Don't worry about the "angle" at which the ends droop, it'll work. Just don't hang them straight down. 90 degrees is workable, more if necessary.

If you can get a small coax out of the house and run it to the trees (or a wood fence), you can run the antenna wire through the trees above head height to keep the kids out of it. You can hang the antenna wires from limbs using small nylon cord or fairly heavy fishing line (don't try the small, low weight stuff or you'll be re-hanging it often in your icy weather). Also if you use common soft copper wire Ice will stretch it and probably it'll come down broken. Soft wire is easier to get but not sturdy, though it'll last a while and can be easier to get. In your case I'd use smaller wire to keep it "clandestine" as possible, generates less inquires = less potential problems. 24 gauge wire can work OK. The larger the soft copper wire the sturdier, but alas, also the more visible. Stretching soft copper "work-hardens" it and makes it a little tougher. But do the measuring after the stretching :-).

Here's what I've done in similar situations. I found a set of swaged aluminum tent poles, the kind that are 2 or 3 feet long and fit together end in end, and I use them to make up a mast of whatever height I can use at a given portable place, usually no more than 10 or 12 feet high. I use them to hold up the center of a 20 meter dipole that is around 33 feet long (two pieces of wire half that long fed with the coax cable in the center at the tent pole), with the ends tied off wherever is handy- tree limbs, wherever. Then when I want to work 40 meters I use 2 more pieces of wire the same lengths with alligator clips on one end, and clip those wires onto the ends of the 20 meter antenna, again hanging the added wires wherever I can. They will be low, but it won't stop them from working. If you do use a rig with an auto tuner (I often use a Kenwood TS570D which can be found very reasonably on the used market. It's a very good and a nice rig BTW and has an antenna tuner builtin-but it's not a single wire tuner)

and it loads this arrangment very well. I recommend it highly if you can find one.
This antenna arrangement lends itself well to "quick setup and takedown" as you may find is needed in your particular circumstances. It can easily be set up to stay awhile, too. I use it lots on CW and HF digital operation in temporary locations.

I have also mounted a dipole directly on a wooden fence, weaving the small copper wire between a few of the upright wooden boards at the top. Works, but not well in wet weather.

If you do decide to go with a long wire and tuner, you'll have to use a single wire tuner such as the SGC or the Alinco EDX-2 which works with their DX70T transceiver. I also have that pair and have used them camping with a 60 foot wire hung wherever I could hang the other end when operating from a motor home, never above 10 feet or so. Using a 40 foot piece of wire lying on the ground under the camper as the "ground" it works well and I make all sorts of contacts even on 75/80 meters. Of course it would work better if it was higher.
Be aware that if you use this sort of setup the tuner needs to be outside the house since it's output is HOT with radiating RF. This means that you will have to be able to exit the house with not only a coax feedline but also a control cable to operate the tuner.

I've always been reluctant to feed a metal raingutter for a few reasons. They are never well bonded together unless they are one piece construction, even then the downspout isn't well bonded to the gutter. This means they won't work right unless you can rework the connections between the gutter parts, and that is usually a very tough and "iffy" proposition. Also the uncertainty of it all means the possibility of high voltages being present in unknown locations, and that's not good for several reasons, one of which is the (even remote) possibility of fire.

Inside antennas have always seemed to me to be a very last resort. So far I've never used one other than an attic dipole when visiting at my daughter's home in a CCR subdivision a few years ago. You'll virtually always experience unpleasant RFI to most every other electronic device in the house.

In any event, you're on the right track. Ask questions and evaluate the answers. You'll learn enough to get something stirring. Remember, it doesn't have to be all that much of an antenna to get you on the air making lots of satisfying contacts. You should have seen what I used as a novice.

And as an HF ham you will probably find that improvement of your antenna situation is an ongoing way of life! Seems there is always a better way to do it that pops up from time to time.

73 and again, welcome to ham radio

<**vk2hxy@hotmail.com> wrote:

|Hi there people, I am new to the hobby, just recently (3 days) got my
|license and am now looking to homebrew my own antennas. I suppose that's
|what makes this hobby so interesting and enjoyable, I love a good challenge.

Congratulations and welcome.

|
|I am looking for information on how to build both a 70Cm and 2 M beam
|antenna. Looking for good proven performers, not looking at conducting EME,
|but would love to be able to make some nice simplex QSO's over a fair
|distance.

Good for you. But don't rule out EME; you say you love a good
challenge :)

|
|I have heard of Quagi antennas for 70Cm, are these worth building over a
|normal driven element type beam, or am I best to start with the basics?

The quagi was an effort to simplify the driven element and derive some
inherent gain from it. I think it has pretty much been determined
that both "advantages" were elusive and the design has fallen into
disfavor.

|
|Which leads me to the next question, what's better a gamma style match or a
|folded dipole DE? and lastly, what's considered better, through the boom,
|or shielded from the boom?

Forget the gamma, especially at UHF. Almost all modern designs use a
folded-dipole or tee-matched driven element. With the greater use of
computer modeling, designs have been developed with near 50 ohm
feedpoint impedances which make possible directly-driven split driven
elements.

There are several element mounting possibilities:

1) Above (or below) the boom on insulators.
2) Above (or below) the boom using metal fasteners.
3) Uninsulated through the boom.
4) Insulated through the boom.
5) Non-metallic boom.

Each has advantages and disadvantages but the differences are
primarily mechanical. The more the element is changed in diameter or

"shorted out" the more correction factor is required, but be assured
there will be an appropriate correction factor for each case, and
these are widely published.

Alan Fowler wrote:
"Now does the current flow up to the sheet, flow out over one side of the sheet, across the edge, back down the other side then continue along the wire---?"

Exactly. When a conducting sheet is impaled on a wire, its skin effect blocks penetration if no hole is left open for the current to squeeze through. Current must transfer from the wire to the sheet`s surface to get from the wire on one side to the wire on the other side. It cannot take the short-cut directly through the conducting sheet or through the wire. Skin effect blocks direct passage.
Best regards, Richard Harrison, KB5WZI

I can say with confidence in my own experience that when you mount the feedpoint of a half wave dipole low to the ground and the ends high, it doesn't work out worth a darn. But when you mount the feedpoint high, and the ends low, it does.

I think we all know where the high current point is located.

You may draw whatever conclusions you wish from that, as I have.

Hello, everyone, and whew! This topic certainly stirs a lot of passion among newsgroup members. As to the applicability and advantages of fractal geometry in antenna design I would look to IEEE publications on the subject. Granted, not all members of r.r.a.a. are electrical/electronics engineers but publication of a paper by the IEEE generally lends credibility to the subject since papers generally require significant peer review prior to publication. One that I found that functions as a fractal antenna primer of sorts is:

J.P. Gianvitorrio & Y. Rahmat-Samii, "Fractal Antennas: A Novel Antenna Miniaturization Technique," IEEE Antennas and Propagation, Vol. 44 No.1, pp 20-36, Feb. 2002.

The above paper is NOT heavily math oriented and quite readable, IMHO. FWIW and sincerely,

George, that's an interesting report and reflects some of my experience at using the Alpha Delta DX-A. My tower is 60 feet with an old TH3MK3, 11 element 2meter yagi and a 5/8 wave dc grounded 2meter ground plane topping the 10 ft. mast. It turned out to be pretty well broadbanded on 160 and worked about as well as the full sized dipole I later put up. I think the tower and its attachments caused it to be broadbanded and to work well, also. No doubt Roy is right, the tower etc does a lot of the radiating. And I always wondered about using one on a pushup mast. Unsurprising to learn they don't perform nearly as well. My DX-A is mounted at 30 feet on the tower.

I can't help wondering how one would model the tower and all that's on it. :-)

3644. Fractal Debate - Defamation

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-02 15:51:17 UTC
From: VE9SRB <srbest@att.net>
Message-ID: <VjLG9.39844$hK4.3548704@bgtnsc05-news.ops.worldnet.att.net>
Source record: 130183

To all Concerned:

I received the following correspondence via e-mail from Mr. Cohen:

>>>>
2 December 2002

Mr. Best--

On the rec.radio.amateur.antenna newsgroup you recently made a public and defamatory statement about me and asserted that my scientific research is not scientific.

That statement is false.

I require a retraction from you on that forum. If I do not see that retraction within the next 48 hours I shall assume that your intent was defamation. If the remedy is not met then I will have to file a civil complaint within the statute of limitations in the Commonwealth.

I assume that you are forwarding this correspondence to your attorney. I will not engage in any correspondence from you or your attorney on this matter and will only respond to a summons with the objective of a jury trial.

Nathan Cohen
>>>>

Mr. Cohen's correspondence was in reference to statements I made on this newsgroup in the thread "Fractal Debate". The statements I made were the following:

>>>>
Had you and the others approached this issue scientifically and even bothered to compare antennas with fractal geometries to antennas having the same physical properties and only differing in geometry, you wouldn't be in this situation.
>>>>

I would like to publicly apologize to Mr. Cohen as it appears that he interpreted my statements to mean that it is my opinion that his work in the area of fractal antennas is "not scientific". My statements were not meant to be defamatory, nor were they meant to express or imply that I perceive Mr. Cohen's work in the area of fractal antennas to be "not scientific".

It is my opinion that Mr. Cohen's work in the area of fractal antennas is, in fact, scientific. I respectfully retract my statements as written and regret that Mr. Cohen misinterpreted them.

However, it is my scientific opinion that Mr. Cohen's scientific work in the area of fractal antennas has not been sufficiently thorough. It is my scientific opinion that his and other's scientific work in this area has been incomplete. I should have written my statements as follows:

>>>>
It is my scientific opinion that you and others working in this field should have approached this issue in more depth. It is my scientific opinion that published research in this field is incomplete. In publishing the performance properties of fractal antennas, it is my scientific opinion that you and others should have compared the fractal geometry antenna designs to other geometry antenna designs having similar physical properties like the same size and same total wire length. In doing so, it is my scientific opinion that you and the others would have recognized that the behavior (lower resonant frequency, higher radiation resistance, etc) exhibited by the fractal geometry antennas is not unique to the fractal geometry antennas. Other geometries having the same physical parameters exhibit similar, and in many cases, improved (better) performance. Additionally, it is my scientific opinion that you and others should have compared the performance of fractal geometry antennas with other geometry antennas where they are resonant at the same frequency. In doing so, it is my scientific opinion that you would have recognized that the resonant performance of the fractal geometry antennas is not unique to the fractal geometry antennas.
>>>>

That was a summary of my scientific opinions and my understanding of our scientific disagreement. If you disagree with my scientific opinions, I would be pleased to debate them as you feel appropriate.

Regards,

Steve VE9SRB

It appears that your problem isn't one of "isn't it science?" but rather one of "it IS psuedoscience". So far your work looks more like that of a charlatan than a scientist. One can only hope that you haven't convinced some clueless procurement officer that the war can be better fought using your Advanced Fractal Antenna Systems in place of "old" technology. As a veteran of wartime military service, to me this is not trivial stuff. Lives can depend on it and probably will.

If your claims for fractal antennas include that they are, as physically smaller radiators, more efficient radiators than conventional geometeries, you simply will not be able to support that contention scientifically. Pseudoscientifically is another matter.

But so far I haven't seen what your contentions actually are. Back when I was interested enough to ask you weren't talking and looks like you're still not. If you can tell us in plain language right here on this NG how you conclude that fractal antennas have any electrical advantage whatever over conventional configurations, you would be well advised to do it and spare yourself, and us all, even further ..... you can fill in the blanks to suit yourself as others will do.

But you can't. Or won't, same difference. If there is no electrical advantage but the antennas work well enough in a physically compressed form to gain a real space advantage for what they actually ARE capable of doing, that alone might easily be enough reason for DOD and others to purchase them in serious quantities, such as was once the case with the B&W HF Terminated Folded Dipole. But if you ever want to see the end of this fiasco you alone hold the key to its finish.

3651. Repeater or Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-02 16:46:02 UTC
From: John Smith <someone@microsoft.com>
Message-ID: <3deb8dfb$1_3@news.newsgroups.com>
Source record: 130190

I am a volunteer for a local Ski Patrol. We are using mostly Motorola handheld FM radio's in the 155mhz range (about 100 of them). We have a base station at the top of the mountain and at the bottom. This year we have added CTCSS and now can screen out all of the annoying other rescue squads that used to dominate us (at the top of the mountain). However, we STILL have not solved our poor coverage problem. Specifically, we have dead zones all over the mountain where we cannot communicate handheld to handheld or handheld to the top or bottom. Sometimes, we can't communicate well even from the top to the bottom. In addition, we have a "back side" of the mountain, where we can only communicate from the backside to the top, and where we would like to be able to talk to the base (at the very bottom).

My question is, would a repeater help this situation the most? Or maybe better (higher) antenna's? Would it be possible (practical) to have a repeater at the top AND at the bottom? Would something like the Vertex VXR1000 connected to our base statations (which are really just mobils with transformers) be of any practical use?

I would appreciate any advice, especially on how to do this on a shoe-string (we are a volunteer organization).

I've posted the question in the equipment group, but thought you guys might suggest antenna's instead.

Thanks,

Mark Rees

Source record: 130192

JEEPMON,
The simplest 'cure' would be to move one of the antennas
to another mounting spot on your vehicle. The next 'simplest'
would be to retune both antennas till you have an acceptible
SWR on both (not the easiest, and definitely not very quick).
When you mount any two antennas that close together there will
be some adverse interaction, just no way around it. You may
'loose' a bit by moving one antenna, but not as much as you
might think, and it'll still be 'better' than what you have
now.
Good luck...
'Doc

3654. Re: Antenna question?

nospam,
As popinted out in another post, it's the height
above ground, not the height above sea level that
determines how 'well' a particular antenna workd.
Being at the top of the hill is 'better' than being
in a valley, but the same antenna in either place
would work about the same (unless your talking about
the bottom of the Grand Canyon).

Brian,
Since the input impedance of a folded dipole is
something on the order of 300 ohms, then a 6:1 balun
should match it to 50 ohm coax pretty well. I have
no idea what an 'inverse balun' would be.

So this antenna was made by Jaybeam (you didn't specifically say so),
and the size and shape of the enclosure are all consistent with one of
their inverse baluns (about 2.5in diameter, 4in long)?

>Can anyone cast any light on this please- I've found nothing on the web.

Unlikely that you would, since it was a proprietary device and the
company hasn't been in the amateur radio market for a long time.

Basically the "inverse balun" was an attempt to make a compact and more
weatherproof version of the half-wave coax balun. This 4:1 balun is
usually made using an electrical half-wavelength of coax as a phase
inverter between the two sides of the feedpoint.

The Jaybeam balun turns this "inside out" by winding an electrical
half-wave hairpin of insulated wire onto a tongue of metal. This metal
is connected to the outer of the coax feedline. The inner of the
feedline and one side of the dipole connect to one free end of the
hairpin. The other side of the dipole connects to the other free end of
the hairpin.

AFAIK there are no published design data for this. The wire and the
metal tongue form a transmission line, and the aim would be to make the
characteristic impedance about 100 ohms (not critical). Also the
velocity factor is not known. However, it did work.

As a further complication, Jaybeam were rather fond of making the dipole over-length and the balun under-length, as a form of reactance compensation to make the whole thing more broadband... or so they claimed.

Jaybeam were always very much into proprietary features with catchy names. They actually did a lot of serious experimental and range work, but some of the innovation was purely to establish a niche in a very competitive market. I feel sure that some of the claims (especially gain) would not stand up to modern examination.

If you were going to copy this dipole, you'd have to copy the physical dimensions of the folded dipole, and then cut-and-try with the inverse balun until you got a good impedance match. Since you can't un-pot the existing unit, you'd be literally working blind. It would be a lot easier to use a half-wave of coax!

Finally, all these baluns we've been talking about are "voltage baluns". Unlike "current baluns" they take no direct steps to reduce currents flowing on the surface of the feedline.

Why not a simple un-folded dipole, with a simple and effective current balun made by coiling up a bit of the coax? The centre mouldings for 0.5in tubing elements are readily available from antenna manufacturers at rallies (hamfests) in the UK.

I'm sure that most of them already sell a pre-cut 70MHz dipole. If you explained that it was for a construction/teaching project, they could probably be persuaded to sell you a batch with the tubing un-cut!

3657. Where to put the wire antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-02 18:22:17 UTC
From: Buddy <noway@jose.com>
Message-ID: <B7EF04C60FE692C3.14D2470A7801E7D8.9543C0DDD30D3338@lp.airnews.net>
Source record: 130196

I'm real close to getting my general ticket. The antenna question keeps challenging me though. I don't have a lot of money to spend or space to string up a dipole in its ideal position. No trees here and a wife who demands an unseen approach. I can't seem to find any real good information which addresses my problem. I'll probably buy a decent vertical or Sigma V when I can get the bucks together.

I'm considering a G5RV or Carolina Windom since they seem to be the best bang for the buck. I have a fairly good size house with 70 ft. of straight eaves running on one side. Wouldn't RF be a problem mounting under the eaves though?

How about over the roof? Like an inverted V? I've got plenty of that. I could lay it on the roof with no problem. Is this a good idea? What kind of problems could I experience?

Finally I could go around the perimeter of the wood fence. It would take one hard 90 degree turn. It would only be about 6 feet off the ground though.

Any help is appreciated.

Hi John,

Given the very limited circulation of this paper, and even more limited availability following its publication, and given resources available on the net already covering this topic - why do you simply stop with reciting a reference and leave us in the cold without synopsis nor comment on its contents?

Did you read it? Do you understand it? What does it have to offer other than the condescending palliative of being dumbed down? What in the course of discussions suggests the topic has a problem of rather simple geometrical or fundamental issues? What does it respond to that has yet to be explored?

This is part and parcel to the heat of this topic: The dissemination of ideas versus the veil of remote references impeding examination as a debate tactic. Citations support arguments, they do not replace their open discussion.

You can kick start your reference with one particular observation:
>>> 'fractals do no better than other small/broadband/frequency
>>>independent/antennas'.

>>>
>>>The answer is 'yes'.
Does your reference respond to the statement and its affirmation?

No? What's the point if it cannot cope with something this
fundamental?

Yes? What's left to say?

3659. Re: Repeater or Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-02 19:04:02 UTC
From: gaschafer@attbi.com
Message-ID: <3debaeed.13895776@netnews.attbi.com>
Source record: 130198

Hi John,

Yes a repeater at the top would solve some of the problems. However
VHF repeater frequency
pairs (frequencies) may not be easy to come by.

The antenna that is on the top may be "too good of an antenna". If it
is a multi element (gain)
type of antenna, the first thing that you could try is to put a
smaller antenna up there. A quarter
wave ground plane antenna would be best. Even mounting it upside down
would help. This will
give some down tilt to the pattern.

What happens with gain antennas that are up very his is that the
pattern goes straight out and
overshoots the lower areas that you are trying to cover. This is one
case where higher gain
antennas are worse than a simple antenna.

Many thanks to Dr. Best for this retraction.

Dr. Best and I have differences regarding scientific issues which do not, and should not, extend to personal ones.

I am of the opinion that anyone who misinterprets our exchanges as ones meant to defame the other is doing both of us a disservice, and Dr. Best has also made this clear by the statement here.

Both Dr. Best and I sufficiently respect each other as colleagues that we understand the need and value of scientific exchange, as part of the process of

enlightening the state of the art.

I believe it is a fair assumption that Dr. Best and I would request that we all try to keep our exchanges civil, and accept that it is possible to have meaningful scientific agreements without any intent nor reason to defame the other.

I enjoy Dr. Best's insight, although I tend to occasionally disagree. I also personally have a high esteem for his experience in antenna engineering, and will strongly request anyone who takes my comments to the contrary to check with me personally.

Thanks all,

73

I'm getting a FT-920 for Christmas and will be using it for just SWL of the broadcast bands until spring when I can get a 6M antenna up. I understand that the 920 has a RCA jack for a receive-only antenna. Short of stringing a piece of wire across the room, is there something else that works better for inside use, and doesn't cost a fortune?

3665. Re: Skin effect - a follow up.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-02 20:01:03 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <uunevufepkm52@corp.supernews.com>
Source record: 130204

Ian has made a very important point here which needs to be emphasized, since it addresses a real problem in understanding skin depth.

You might have read on this newsgroup or elsewhere that skin depth is "defined" as the depth at which the current density drops to 1/e (about 37%) of its value at the surface. I hope I wasn't one of the guilty parties that made this statement -- if so, I apologize and retract it. I think this misstatement is the cause of some of the misunderstanding of the meaning of the term.

It would be correct to say that the skin depth is defined as the depth at which the current drops to 1/e of its value at the surface *in an infinitely thick, homogeneous piece of the specified material*. Therefore the skin depth, as Ian points out, is an intrinsic property of the material (at a given frequency, since skin depth is also a function of frequency). This means that the current density doesn't necessarily drop to 37% of the surface value at one skin depth in all shapes and thicknesses of the material -- only in material that's thick enough. The skin depth remains the same regardless of the size or shape of the material sample; the shape of the current penetration - vs - depth curve does not. However, it does follow the nice exponential and easily calculated decay any time the conductor is at least several skin depths thick (and the curvature of the surface is small on the scale of the skin depth).

As I and others have pointed out, at HF and above, the skin depth is very shallow in good conductors, so the assumption that a physically useful conductor is at least several skin depths thick is nearly always a good one. And the current density will decay to 1/e its surface value at a depth of one skin depth provided that this assumption is valid. However, this is not the *definition* of skin depth.

Steve has backed up his opinions with several papers in professional publications. In addition, he's furnished some simple examples of randomly-bent wire antennas whose properties are equal or superior to a fractal antenna widely used to illustrate the fractal technique. EZNEC users can download EZNEC description and antenna notes files with these examples from ftp://eznec.com/pub/MI2/. Please see the 0notes.txt file in that directory for descriptions of the available examples.

I have a dipole strung inside my apartment, along the cathedral ceiling, out to the walls and down the wall some. I used 16 gauge speaker wire, fed it with cheap 300 ohm TV line through an old MFJ tuner. That, along with my TR-7 and 50 watts, I never long for a contact. Try anything, you might be surprised. Dick,

Are you working on the basis that you are one of 50,000 old-wives who can't be wrong. This is radio - not a detergent powder!

The fact that in many cases antenna efficiency appears to decrease when the high-current parts are located nearer to the ground has no bearing on what parts of an antenna "do most of the radiating".

==========

You don't say what conclusions you have drawn. Have you considered the radiation pattern may change adversely when switching between Inverted-V and V antennas?

Have you considered dependency on ground conductivity and that opposite effects may be observed with high resistance soil. It depends on HOW the antenna is coupled to ground loss resistance - inductive or capacitive - via the antenna middle or its ends.

Radiation resistance depends on the degree of coupling between antenna and ground. But this behaviour throws no light on what parts of an antenna may radiate more than others, if any part radiates at all.

For calculating purposes an image antenna is sometimes supposed to exist below ground. Its imaginary induced currents and voltages can be calculated along with the distant fields they produce. Combined with the field from the real antenna the resultant computed far field is correct.

Yet the image antenna itself is non-existent. Does the image really radiate? What a computer program thinks it does may bear no resemblance to what happens in the real world. Another program may be brainwashed into thinking the distant field is the resultant of the direct wave and its reflection from the surface of the ground. If the answers are correct who cares. But be on your guard when attempting to extrapolate from what the computer thinks it is doing to conclusions otherwise unwarranted.

Would you infer radiation occurs mostly from the ends of a dipole if greatest loss occurs when the dipole ends are nearest to very high resistance soil? (Is the soil loss resistance now better matched to the generator?)

With a near perfect ground efficiency won't change with height of the apex of the V. That will certainly tell you nothing about what parts do the radiating.

I agree, as a rule of thumb, if you have a V above ordinary sorts of ground then invert it with the apex at the top.

==========

PS: No part of an antenna radiates. The radiation field is zero on
conductor surfaces. Energy becomes detached from the near-field with
increasing distance from the antenna because the near-field doesn't have
sufficient time to fully collapse back upon itself during the
radio-frequency cycle. The field velocity is restricted to that of light.
The energy detached gets lost in space and changes its name to Far Field.

There must be a mechanical analogy somewhere.

Reg, G4FGQ

Source record: 130208

Under the eves has too many problems. It is likely to interact (both ways) with house wiring, and it is unlikely to load (with a modest SWR) at anywhere near the calculated lengths. On the roof is not quite as bad, but should be a last, last choice. Either one can make QSOs, but I suggest you try for something a little better.

Can you not go from one end of the roof ridge to almost any support. The higher, the better of course --- but something only 10' up will work. It will work better on the higher bands, but it will work to some degree and make many QSOs on any band. (Well, maybe not 160!) At this stage, a primary requirement is to keep it high enough so that no one can walk into the wire (or reach up and touch it). Also, you need to be concerned about feeding a dipole; you need enough coax to reach the center and the coax needs to be routed in some way that people do not walk into it, etc.

For any low dipole, the calculated lengths will not be quite right. Start with wire a little too long and trim (6" at a time) until the SWR is reasonable.

You did not say what band(s) you plan to use. If you have an antenna tuner, you can make better use of any dipole---at the expense of having to adjust the tuner every time you QSY.

Bill

EZNEC is a commercial product which, as you gathered, operates only under Windows. The reason for this is simple: the customer base for Macintosh, Linux, and other operating systems is simply too small to justify the time required to develop versions for these systems. Some people who do want to use operating systems other than Windows and at the same time have access to some of the richness of applications available for Windows use emulators to run Windows software. Although I can't guarantee that EZNEC will run on a particular system with an emulator, I've gotten a number of reports of success using it with emulators.

I suggest you take a look at http://www.qsl.net/wb6tpu/swindex.html. You'll find free antenna analysis software there compiled for Linux by people who have done it as a labor of love. NEC-2, which is free, will produce the same answers as EZNEC and similar software, although with a somewhat more cumbersome user interface.

I never was much of the "gun rack" type. I once had a truck with a gun rack, but I kept a huge 3-4 ft long adjustable wrench on it. It got as much attention as most guns, and nearly as deadly if I were to plonk someone over the head with it. If I have guns, I hide them. I like to be sneaky. Gives me that "Clint Eastwood" edge. Kind of like having the sun behind you in a shootout. I rarely have guns unless I'm going out of town to the boonies somewhere. I'm not going to bother getting a permit. I don't need a permit to carry a shotgun. Or a handgun either as long as I'm traveling out of the county.

Bravo! This retort would have given Perry Mason a hard on. A summary
of scientific opinion that should rate two thumbs up at the next great
frectal debate. Your restraint against such goofball and paranoid
accusations deserves special mention.

Myself, I would have told the little antenna weasel to bite me, but I
don't have to protect my image being I only make antennas for myself.
Everyone already knows I'm an asshole. Being I are one, I know how to
deal with other assholes in an ugly and efficient manner. But your
retort should have him squirming on the hook for a while. He'll be
trying to find a way to accuse you of having the wrong opinion, and

that you should cease and desist at once. I had thought in the past few months that he was showing improvement, and that surely his recommended thorazine therapy was paying off. But crap, I was wrong. He's just as paranoid and goofy as ever. He's been spitting the pills out again while the nurses aren't looking. MK

I think everyone is missing The Point!

The Point *is* that Dr. Cohen promised to produce a fractal antenna design
by the end of October that
is optimum under the Figure of Merit which he demanded from you on *very*
short notice, and that you
so graciously supplied at his request. The Point is he didn't deliver, as
usual!

The "fractal braggart" has failed again and has not delivered said optimal
design! That is The Point!

The threat of litigation is just more obfuscation on the part of Cohen...
reminds me of Humpty Dumpty.

I just wish Cohen had publicly appologized to me after he "trashed" me and
offended my
technical reputation publicly on the NG. But then none of his arguments
ever has symmetry!

For those who don't recall some of Humpty Dumpty's obfuscation and fussiness
about the meanings
of words compare Cohen with Dumpty... [scientific reputation indeed!]

--
"When I use a word", Humpty Dumpty said, in a rather scornful tone,
"it means just what I choose it to mean, neither more nor less."

"The question is", said Alice, "whether you can make words mean so many
different things."

"The question is", said Humpty Dumpty, "Who is to be master: - that's all."

Lewis Carol, "Alice in Wonderland - The Turtle soup"
--

I am afraid that Dr. Cohen will never be Master, as long as he "sits on that wall", heh, heh...

I (safely) assume that the near-field expanded at no more than the speed of
light. Why can't it collapse at roughly the same speed ?

Hi Buddy,

There are several commercial verticals that are designed for QRP use but will work up to 100w very easily. They have the advantage of being put up and taken down in a few minutes. With an antenna analyzer you can set one of these up in no time. They pack away into a small space when you're done.

Another alternative - nurseries will sell large trees and plant them for you. You can stick them where they'll do the most good as antenna supports.

Good Luck,

Bill, W4WNT

Could you share some light on this? I'm trying to grasp
how to make a broadbanded yagi(perhaps) for perhaps 2.4 to
2.5. Or How does one design a TV antenna(I want to get
channel 38 and channel 56 in for once and all)?

Another question that I have been wondering about. How does
the surface area of the elements effect the results? How
does a solid element versus a hollow cyclinder affect the
equation?

Hi All,

Given Jeff's lead to the source document, it would seem the answer is No, it does not respond to the statement at all (or is deeply buried - same thing). In all practicality, not very useful at all.

It does, however, provide an alternative coverage that supports many of the issues I examined at my pages. This researcher may even come to describing a "general" formula, a work in progress that can already be found at my site. I will admit this work is stale and some 3 years old. Now that fractals have fallen on hard times, I see no need to complete it (I will leave that to a doctoral candidate so that there is more paper ballast available for the library stacks).

Further, it is becoming increasingly obvious, through the repetition of examples that fail to reveal any new geometries in the past 8 years, that this "science" is dreadfully in-bred and constitutes nothing other than book reports on prior work; or, at best, class construction projects. That it duplicates work I have done in years past also begs the question of what constitutes research when it has all been done before, over and over and over. That it fails to encompass the small scope and range of forms I have committed to my pages reveals a poverty of results from research in these past few years.

Others might not have to fight the yawns reading this - their mileage may vary as the saying goes.

I guess in a place like Texas a man needs a gun in order to make sure he
sees his next birthday. It's different in other parts of the U.S. where people

are more on the civilized side.
I used to do a lot of hunting when I was young. I'm not bragging when I say
that I bagged more stop signs and tin cans than anyone in Tulare county in
the late '50's. And all I had was a single shot .22. Other people shot
rabbits,
dove, etc. Those critters had nothing to fear from me, though. I couldn't hit
them, anyway. I was always after bigger and bigger road signs.
Have you ever shot up a road sign, Mark? Don't lie.

Only a simple one, that is, for a dipole to be an effective radiator the feedpoint needs to be elevated while it makes much less difference about the ends. Found that out the hard way long ago at age 14 with a new Novice ticket. Not exactly rocket science and for sure not a full investigation of the electromagnetics involved, either.

Bill, KB1UB wrote:
"Could you shed some light on this (broadbanding)?"

Art Unwin may explain his broadbanding system.

Arnold B. Bailey in "TV and Other Receiving Antennas" about doubles the bandwidth of a 200 MHz dipole by increasing its diameter from 0.5 in to 2.5 in. This shortens the dipole from 25.4 inches to 22.7 inches. 200-MHz feedpoint resistance also drops from 49 ohms to 37 ohms from the increased diameter.

Broadbanding a yagi is complicated because more variables are involved. Perhaps the ARRL Antenna Book will help. You can choose the characteristics you want to optimize. They don`t all peak at the same place.

L.B. Cebik wrote the "Log Periodic Arrays", Chapter 10, in the ARRL Antenna Book (19th edition). For more information visit his weebsite. Just search on his call sign, W4RNL. Click on "Tales and Technicals". Then choose "Log Periodics".

TV Chan. 39 is 620-626 MHz. Chan. 56 is 722-728 MHz. Log Periodics scale to TV frequencies from H-F. The UHF TV version may be only 1% of the H-F size.

Solid elements don`t help much with strength. Nerarly all the stress is in the outer "fibers" of an antenna rod, and nearly all the r-f current is right on the surface of the antenna element. Tubes make the best use of the antenna material at UHF.

Best regards, Richard Harrison, KB5WZI

Mark:

Unfortunately, you need a real professional to address this problem. I say this because the suggestions Gary makes will be typical of what you get from volunteer help. His problem analysis is correct, you need the correct antennas in the right locations, but the old wives tale about hanging one upside down doesn't help much. The additional scattered signal you may get is unpredictable and results from uncontrolled pattern distortion.

You also misunderstand the effects of CTCSS. Those other signals are still there, and will sometimes cover up your HTs even though you no longer hear them. Push the defeat switch when a unit doesn't answer, and see if there isn't another strong signal already there.

Antennas are made with engineered amounts of "downtilt" which is what you need here for the top. Several manufacturers make downtilt antennas for 155 MHz, but none are cheap. For the bottom, you need a professional to look at the requirements and "lay of the land". You probably need a "keyhole" or some other shaped pattern antenna for the bottom, but that is a WAG. You need to find a wealthy benefactor to fund some system design engineering to get a properly working system. Manufacturers never did that very well, and seem to have given it up altogether these days.

Actually, they work better (at least at my QTH) at 2-3 ft off the
ground. Amazingly, my 520 ft beverages work even down to 1000
kHz and below. I picked up WCBS in NYC on 880 kHz from the
west coast with one of my beverages. My ground conductivity is
so high that 1300 ft beverages are no better than 520 ft beverages.
In any event, beverages blow the doors off of loops, which blow
the doors off of random wires of any description.

Hi Rick,

When I was a teenager in Colorado Springs (mid 60's), I could get both coasts (SF & NYC clear channels) with a 50 foot antenna 5 feet off the ground strung up along a fence. My receiver was a Navy surplus RBB-1 (there is also the VLF band RBA and HF band RBC) which tuned AM in either two or three bands. The dial had a 10KHz resolution that was a quarter inch wide. That sucker could sub for an anchor with a bulk of 24" X 24" X 24." Add to that its power supply (at 12" X 24" X 24"), then the 1" thick lead with a couple dozen wires between them and you get my drift. I also used to listen Wolfman Jack out of XELO, Del Rio Texas (or maybe it was XERB).

I did a few quick comparisons between a 16 inch loop, and my "T"
vertical, which is about 42 ft tall, with a 120 ft long flat top wire.
It's pretty hot on MW. The radio was my ic-706mk2g. I'll let the
recordings speak for themselves.
You can click on the URl for the sound files, and your media player
"should" bring them right up and start playing. Hopefully anyway...

I did three tests, on three different frequencies, at different times
in the evening. I'm in Houston, and used mainly San Antonio as the
"target" city. "good 200 miles away" I recorded each test. I did
compress the audio greatly to save d/l time, but the audio is still
good enough to tell which is best. The files are pretty small and will
d/l quickly. They were huge files in the original sample rate and
format...I will "narrate" each test, so you will know which antenna
was used, and the exact times I switched. You can use the counter in
the media player to keep track of the time.

Test #1 was at about 7:30 PM on 550 kc.
http://web.wt.net/~nm5k/mwtest1.mpeg
"Time in seconds"
0-13 -----loop
13-26 -----wire
26-38 -----loop
At 38 seconds I nulled the station, so you can hear the null.
46 -----loop, back pointed to the station
57-69 -----wire
69-end -----loop

Test #2 was at about 8:00 PM on 670 kc.
http://web.wt.net/~nm5k/mwtest2.mpeg
"Time in seconds"
0-11 -----loop
11-23 -----wire
At 37 seconds I nulled the station
46 -----back pointed to the station

55-67 -----wire
67-end -----loop

Test #3 was at about 9:00 PM on 570 kc. Multiple stations on this freq...
http://web.wt.net/~nm5k/mwtest3.mpeg
"Time in seconds"
0-10 ----loop
10-23 ----wire
23-37 ----loop
37-48 ----wire
At 62 seconds, I turn the loop 90 degrees to get a totally different station.
At 74, I turned back to the first station.
85 ----turned back to 2nd station again
91 ----back to the first

Anyway, you all be the judge. Myself, I prefer the 16 inch loop anyday over a long high non directional wire. Yes, it's quite possible beverages or whatever could beat the loop, but you are talking a lot more work and wire. And it still wouldn't null as precisely, unless I had beverages in every direction. MK

really? you think 30 million plus users of linux is too small a market share (and growing by 4 million anually)? as for mac, et al, they aren't as small a market share as you would think, given the amount of space dedicated to mac product lines at places like Fry's electronics, Best Buy, Circuit city, and others... In fact, some of the software and products for these systems (such as linux, mac osX) are available at staples and office max! I'm sorry, but you are writing off a substantial market share based on an assumption.

3712. Re: Fractal Debate - Defamation

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-03 10:51:22 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <uup35fta49mpc8@corp.supernews.com>
Source record: 130101

The last time I looked, the Linux PC (not server) user base was around 1% or of the Windows market, with a total of about 3 million vs. 240 million for Windows. (See for example http://www.alliedcomputing.com/default.php?news_id=50.) But regardless of whether there are 3 or 30 million Linux users out there, if they were to buy EZNEC at the same proportional rate as Windows users, there wouldn't be enough to make it worthwhile for me to pursue. Unless maybe they'd pay $9900 or $990 per copy instead of $99?

But for you and others who think the software developers are missing something, my advice is to go for it! Don't waste your time cursing the dark, invent a better light bulb! Think of all those 30 million users out there with their checkbooks practically open, ready to write you a check! NEC-2, a little GUI, and you're on your way to riches!

Those 30 million people are waiting with bated breath and open wallets -- don't let them down!

And no apology necessary for the rant. Everyone is entitled to his opinion. I get lots of advice on programming from people who have never done it, and on child rearing from childless people, too, so it's nothing new.

Think about this. As the current flows up one side
of the sheet, around the edge and down the other side.

Now think about "proximity effect". This is the
reason the current flows on the inner surface of the outer
conductor in a coaxial cable, and the outer surface of the
inner conductor.

Alan.

Hi Ted

Thanks for your reply.
I will consider mounting my HF6V the same way.

Mogens

I think that was far more than I expected you to admit. Of course there are many more details, and one might speculate that some of your clients have been very, very interested in what you are alleging is a "scientific scam"-- to quote you.

Just because they have not made progress may, you know, indicate the wrong people for the tasks at hand.I would also be very concerned about delving into using other people's IP--but that's just a thought.

I geuss everyone wants an edge these days.

Trying to render an inventor as absurd is not a successful way to acheive that, and you may wish to reconsider such a path.

If I were you--and clearly I am not-- I would minimize exposure and maximize fact.

Best of luck,

73

Why can't it collapse at roughly the same speed ?

==========

It does, but it's obvious it always starts back too late. Even at the
velocity of light it needs time to go to a given distance from the antenna
and then come back to where it started. You disappoint me.

You could use a gainful antenna (a mini beam affair) and point it directly down the hill.. not straight out. One each side of the mountain.. ? For this you would need some sort of matching/phasing unit to operate 2 antennas in TX mode at the same time...
remeber.. point down not out.

Exactly where is the wattmeter located?
Is the 50W reflected flowing back into the transmitter?

No, it's because each of those conductors generates its own skin effect.

Skin effect is generated *locally* on any conductor, independent of
whatever RF circuit it happens to be part of.

In part, perhaps, as the transmission line has series inductance.

According to Terman`s 1955 opus on page 23, "Proximity Effect" is "skin effect in coils". Proximity of conductors carrying current in the same direction boosts resistance over simple skin effect because like charges repel each other and concentrate the charges away from other. This boosts the effective resistance. I would think the same effect would appear in conductors carrying current in opposite directions as the attraction between unlike charges would concentrate charge in proximate areas of the conductors.

In a transmission line, the transverse voltage has opposite polarity charges facing each other.

Facing transmission line surfaces have incident currents inducing opposite direction currents in each other. These motivate current within the coax rather than outside the coax. The potential difference is between the inside conductors. The outside of the coax is shielded from the inner conductors by skin effect.

Best regards, Richard Harrison, KB5WZI

I have a Butternut HF9V vertical and I have it ground mounted. I purchased
a tilt-over device for it from Gap. I'm very satisfied with it. I never
have to worry about high winds again. When it's threatening out I go out
and in about 2 minutes I have my vertical laying on the ground. Don't let
anybody tell you that a vertical won't permanently bend in high winds, they
will, it happened to me.
My 2 cents worth .

Benson,

If you can possibly do it, an outdoor antenna is the way to go. Barring that, a loop antenna for the MW broadcast band and a wire for SW broadcast as high as possible and as long as possible would be good. If you have a particular band you are interested in and can put up a half-wave dipole for that band, you should have good results. Indoor antennas are noisy.

Fact is...

You came back into this Newsgroup a few months ago, spoiling for a fight
with the
genteel Dr. Best, and begged Dr. Best, or anyone, for a quantative FOM.
Well Dr.
Best delivered a valid FOM within a day, and then... *you* promised to
deliver a
fractal antenna design optimized against that FOM by the end of October,
and...

You didn't!

Game over you set the rules, made the boast and... *you lost*!

This kind of "bait and switch" and failure to deliver has been an earmark of
most of your
postings on this NG for the past several years. I have seen no difference
or improvement in
your approach to others here from whom you seek approval.

No one denies that antennas with fractal geometry radiate, they do and
that's a fact, heh, heh
but... that is not your scam. Your scam comprises the outlandish and often
absurd claims of
optimality and originality and the accompanying boyish and booring boasts,
braggadicio and
idle threats of litigation thrown out to all at hand.

I say... go peddle your "fractal is the best thing since sliced bread" and
"I own all the patents"
Na, na, na nana... scam elsewhere where there might be innocent souls more
gullible than
the present audience.

Richard do you have a reference that I can look at regarding
clearance required. I have always just made a hole big enough
so that insulated wire could go thu but water was kept out!
This would be a good time to correct this practice.
Thanks
Art

Crazy George is not crazy at all. "Private Line" is not private at all. It only squelches the competition for the channel in your receivers so you don`t listen to all the other users. They are still using the channel and this is often when you would like to use it.

Multiple repeaters can be used to fill in the dead spots and voting receivers can be cordinated to select the response. It is complicated and costly. A professional is called for if Motorola won`t do it for you. Remember that their interest may not be exactly coincident with yours, in the short term. Motorola certainly has the expertise in-house if they choose to do the customer service.

Art, KB9MZ wrote:
"--do you have a reference that I can look at regarding clearance
(around a wire)--?"

I don`t remembr the attenuation or where to find it. An internet search might find the answer. Metal casement windows can be closed on an aerial wire fairly tightly and the signal gets around and under them. The attenuation may or may not be noticeable. I remember an illustration of pyrex insulators in a metal bulkhead which was at least twice as bad as parallel wires through the same hole because the same current magnitude was getting two bites taken out of it by going through two holes. The metal has opposing currents induced into it.. But if there is no loss in the metal? Parallel wires going through the same hole have opposing currents nullifying the external field
to a large extent. I can`t quantify it off the top of my head.

Best regards, Richard Harrison, KB5WZI

Thanks, Bob. I think I can get a piece of coax to the outside, then get
a wire up into a nearby tree.

I will have a ground rod very near where the coax comes into the house.
What is the wisdom regarding static/lightning protection? Put a
Polyphaser-type device adjacent to the rod?

Hi Richard,

This is ameliorated by merely separating the loops of the coil at
least three wire diameters.

Hi Eric,

If this group is representative (and it is THE place to come speak to the author); you are the first in my knowledge to have asked since 1995. So much for the reputation of market share as a reliable argument. If YOU are representative of that other share, you might want to think about survival and the propagation of the species given the incredibly thin numbers by this same representation as an expression of share. The population "might" double in 10 years? That is absurd as a statistic of health given that flavor of the day computer languages disappear faster than that. I am fluent in at least half a dozen extinct languages myself - more if I count dialects.

I have Linux, and I know how to emulate Windows (I also have Windows). A Mac? I've always been amused how those owners scramble with a system crash - so much so that it erases their short term memory and they continue to gush how stable it is. :-)

You failed to mention UNIX, OS/2, (I hesitate to offer CP/M) and so on that still runs on machines in closets (talk about market share). You also forgot to recite that there are more servers running on Linux than any other system. Good reason too, but it fails to illuminate the fact that most of those servers are in the same closets as the old CP/M machine - not in commercial service.

The answer is to write applications in a Network Language (not an OS language) like Java.

Hi Mark,

This was a neat idea and I was very enthused to give it a try, but for some reason nothing happens when I go to the page. I tried with both Netscape and IE and nada (last night and again this morning).

Any hints?

With terrestrial radio the distance is short, with no noticeable delay.
There are no service provider charges. With satellite, the delays are
the pits for 2-way conversations. Satellite is fine for broadasting or
data, but phones? Terrible, even for half-duplex, in my opinion.

Power out of the transmitter = ???

Assuming a Bird meter in a 50-ohm coax of negligible loss, power out of the transmitter is equal to that delivered to the load, and that is by definition the difference between the two readings. In this case it is 100 watts.

It is not a old wives tale it is a fact and does indeed work. I have done so and KNOW it works. Who cares if the pattern is distorted? Is that now what he wants to do?

Certainly he would do better with 'professional help'. But he also stated he did not want to go to that kind of expense.

Your comments infer that ham radio operators in general have no knowledge or 'wives tale knowledge' I take as offensive. I for one have plenty of practical experience and I will hold that up to any wizz kid and his paperwork degrees.

Gary's suggestions were practical, and technically sound.
So the disparaging tone re his post was uncalled for at best,
and rather rude.

This IS a case where a simple "no-gain" vertical would outperform
a fancy phased array with a pancake beam. It shouldn't matter much
whether said vertical is a dipole, coaxial dipole, J-pole, or ground
plane. But any location on the mountain side that you can't see from
the antenna location may nevertheless present a coverage problem.

It is not clear whether or not Gary misunderstands CTCSS; so the
polite thing to do would be to give him the benefit of the doubt, and
assume that he understands it OK. But the observation that CTCSS
merely masks co-channel interference is certainly correct.

Is it necessary to share frequencies with the other groups, in an
uncontrolled fashion? Or could you (Gary) conceivably get together
with them, and agree on a non-interfering band plan?

That would probably be the case here also. Our ground quality is
fairly decent.
I wish I had the room to lay out beverages here, but I'm on a city
lot. I do have a place up in the country north of here where I would
have the room. But I don't get up there very often lately. There is no
power up there, but that would be no problem being I run off of
batteries anyway. Next time I go up there, I might take some wire and
try some temporary beverages just strung where ever.
Sometimes I wonder about using a single wire from one of the long barb
wire fences to try as a long antenna, but the rectification problems
from rusty connctions, etc, would probably ruin that idea. I'm sure
the beverage would beat a loop on real long haul dx. I think the loop
is well suited for general use where the main problem is seperating
the different stations, rather than sniffing out very weak dx signals.
I've been considering a set of short phased verticals for 160m dx
listening. They would probably do well on MW also. I'm lucky to
squeeze a 160m dipole on this lot, and I have to bend the legs back
into a "Z" to manage that. 80m is the lowest band dipole I can get in
a straight line over the house. MK

Worked just fine for me, using my browser of choice (iCab 2.8.2). Each file was automatically handed over to QuickTime which processed it immediately. I listened to all three clips.

Just to check whether older browsers work, I tried Netscape Communicator 4.8 (the most recent version of the venerable 4.x Netscape series). Worked fine, but I had to download the file and submit it to QuickTime by hand, rather than see it handed over to QuickTime automatically. I then tried Mozilla 1.2.1 (released last night) and again I had to download the file separately and hand it over to QuickTime. Mozilla, as you probably know, is a work in progress, and is about a half year ahead of the Netscape releases (e.g. Netscape 7 is pretty much Mozilla 1.0.1).

I won't have Internet Exploder on my computer, for security reasons, so I can't tell you about that one.

Oh, by the way, all this was done on one of those "unstable" Macs -- a year and a half old G4, to be specific. iCab isn't available for Windows, which is a shame, since it is such a nice browser. And this particular Mac is still running OS 9.2.2, and is not yet on OS X, which in case you didn't know is really UNIX (something like the BSD version) with a pretty face. I think UNIX is considered to be rather stable.

What the hell are "Disruptive technologies"?

The only ones I can think of in the last hundred years or so are the
automobile (scared the horses) and nuclear weapons (scared everyone).

You only "Wish I knew who you were" so you could send one of your childish,
paranoid threats of a lawsuit for impinging on your "scientific" reputation.

> Why can't it collapse at roughly the same speed ?

"Reg Edwards"
> You disappoint me.

I'll have to try to come to terms with that a bit later (*).
:-)

> It does, but it's obvious it always starts back too late.
> Even at the velocity of light it needs time to go to a given
> distance from the antenna and then come back to where
> it started.

Sorry to be slow on this, but the speed of light seems like a red herring because it obviously contrains the speed of the expanding field exactly the same way as the collapsing field. Is this another of those weird cases where 'playing the film backwards' (reversing time) wouldn't work ? Is there a frequency that is sufficiently slow that it won't radiate at all ?What is the obvious bit that I'm missing ?

I appreciate your time.

(This reminds me of my previous innocent question about the relative phase of the E and H fields - in phase or quadrature [answer= in phase]. Sometimes the very simplest 'basics' get missed.)

(*) Something to keep in mind is that a child can ask "Why is the sky blue ?". The question is easily answered with elementary physics. But the child only needs to ask about four or five more follow-up "Why?" questions to hit the 'bottom of the well' of human knowledge. It's rather humbling for humanity (at least it should be), and it is also reassuring for those of us that don't know everything (yet). :-)

Theoretically it would be 100 watts out BUT the SWR is going to be high enough that most modern transcievers will cut the power back to something substantially less to prevent damage to the transciever.

Get a copy of the tech manual "Now You're Talking". That will give the theoretically correct answer. As several have stated though, your radio will either cut back or die if you run very long at that rate.

Hi David,

Then that must mean you are our token Mac user. OS X is really UNIX? 'Bout time, UNIX has been around for a quarter century or more. Nice to see Apple has cleaned up its act finally after 10 years in the wilderness, but that sidesteps the fact that Apple has been using derivative technology since its inception. [This is not to elevate Microsoft stock, or the perception of worth for Windows - it ain't there either.]

Its a shame that Apple decided to pull the plug on its clones, their market share would've been on par by now but they decided to use fractal marketing techniques.

Ah, Reg, that may well be. But you and they may rest assured that I have no problem with being quite sure which part of a dipole to elevate in order to cause it to work as needed, which is to say correctly. As long as it does that, who cares how it wants to radiate?

Roy,
Re Combination dipole/loop aqntenna
Frankly I haven't achieved anything with respect to the antenna.
I surely over estimated my abilities when I decided on this antenna.
I am a total failure so far with as many steps backwards as forward
First I decided that 1 1/4 I.D. would not be increased...big mistake.
The capacitor is made from a florescentlight tube strengthened with a
coat of epoxy, my clumsiness defeated the epoxy many times. Wires for
the stepping motor plus a relay for swiching door knob capacitors so I
could creep up to 2000pF also took more room. The plastic belting used
to move the capacitor plunger seemed to weak for the job which has
forced me to metal, a direction that I did not want.All of the drive
belt must be encased in its own tubing to ensure no tangling.
So much for whining and excuses.
Now it is a battle of me against age and the cold but to change ideas
now inferes defeat, it will be completed, just longer than I thought
and maybe not this year! Tomorrow is another day tho!
The center portion of the element is aluminum tubing, the rest being
thin fibre.
Foil covering is thicker than past use at .002" and comes with a glue
back
which allowes me to go end to end of the radiator without a break.
In the past I had an inkling to try anti static material, I am really
glad I left that for another day (sprayed metal on mylar, very thin
metal shell !)
It will be used for all bands from 1.8 meg and up as in the past, tho
it may well have four lobes on 28 meg but with more than normal gain
.However the top bands are my interest at the moment as far as
rotatable antennas go.
In retrospect I should have put some of the innards just under foil
rather than within the tube. Now the battle is just for survival
rather than the particular experiment I was attempting which I imagine
the metal drive chain will now defeat.
The auto control will be by a computor chip (bs2sx, stamp) which is

waiting for the cold to drive me inside,hopefully this way I will be able to garnish some facts over time with respect to frequency vs capacitance versus SWR and radiation patterns.
Now, after stating all that I assume that the derision will start all over again.
The song 'Mad dogs and Englishmen....." explains my actions quite well.

Regards
Art

Hi Richard,

I thought if I gave you time enough, LEOS would come to mind. There
are more services than telephones though. If not already in place, it
will come to pass soon that every plane and ocean going vessel will
have an emergency transmitter looking up. Personal models, if not
already available, will become as common as GPS for those who travel
in the mountains.

I've a buddy in SAR here in the Cascades and his group never really
came together effectively until they got serious and went into the
grant cycle. THAT is the cheapest route hands down.

It appears from his original message that his "balanced antenna" really isn't balanced at all, given that one side of it touches pine tree limbs. That causes unbalance will surely cause common mode radiation on the twin lead which *will* induce into the house AC wiring as the feedline transits through the house to the shack.

I'd try a piece of good coax long enough to reach well outside the house, with a good choke balun installed just before it transitions to the ladderline.

No, not such a good answer.

If the transceiver has cut the power back to substantially less than 100 watts, how did the wattmeter come to read 150 watts forward and 50 reverse? Suppose the transmitter has cut its output power back to, say, 50 watts. The original posting said that the wattmeter reads 150 W forward and 50 reverse, which is 100 watts of real power. So where did the other 50 watts come from? No, if the transmitter has cut its power back, it's cut it back *to* 100 watts, not *from* 100 watts.

If the wattmeter is reading 150 watts forward and 50 reverse, there's 100 watts flowing through the wattmeter, delivering 100 joules per second of energy to whatever's connected to the wattmeter output. Period.

Come back, now there's a red herring. "What" is it, that "comes back"
like a bad penny? A cloud of electrons? The ï¿½ther? "What" usually
denotes a physical manifestation (the "it" of "it comes back"), except
when used rhetorically as a question - but that would seem to work
too. Is this the propagation velocity of a lame joke?

Any physical entity traveling at the speed of light, suddenly "coming
back" would have the sum total power of the Universe expended in a
whiplash.

I know that it is more than Mexicans that are illegal now. When the
U.S. in the late sixties decided not to continue with the normal West
European which are white and changed over to a system where whites do
not rank in the first dozen
immigrant countries. Now the U.S. is seen as the most wide open
country in the World today for immigration where the quickest way to
citizenship is to arrive illegally and wait for the regular pardons
that occur. This means that immigration is more than double that the
government will admit (reason for the pardons)Don't worry, I have run
into lots of English that are entering illegally
instead of waiting for years of no hope and it may well be them that
take your car now. Everybody knows that illegals are not deported now
or even reported by the police so certainly none of the 'illegals' are
down trodden today.
Ever thought of being a guide at the Nation Monuments to help
immigrants understand what America is all about? They do have money
even tho they may
be Arabic.

Home building supply or electrical suppliers sell a bimetal clamp designed to be used with copper/steel ground rods that allow different metals to be joined without electrolysis problems. I'd get one if you want it to be reliable, and I'd find out for sure that it IS one that will work with aluminum. Losing your ground without knowing about it can be dangerous, even deadly.

I guess all that means you haven't calculated it. I had thought you would, since you seemed to show quite an intense interest in how the current varied with depth in that material. And the calculation, which involves no more than high school math, would be simple for a mechanical engineer like you. I guess I misunderstood your earlier postings -- I thought you were interested -- actually very interested -- in that topic. Once again I guess I didn't understand what you were trying to say. Sorry.

JELo,
Actually, there is something you can do to
help these metals make better contact in addition
to the recommendation above. This technique does
take time and some preparation. It's much easier
to do before the actual installation, but can be
'retro-fitted' with slightly more effort.
Find a quiet spot where you can be alone with
the various metals involved in your grounding project.
Calmly speak with each individual metal about the
various merits and desirable qualities of the other
dissimilar metals. Extoll the virtues of each to
the other. If you do this correctly, there will
never be a problem about loosing ground because the
dissimilar metals dislike each other.
Another method is to hire a midget belly-dancer to
jingle-jangle her way around the grounding site, while
you paint your self blue and do 'rap' recitations over
the connections to be made. (It helps if the midget
belly-dancer is of Lithuanian extraction.)...
'Doc

PS - It works, but this is a bad time of year to be
doing it, unless you live south of the equator.

==========

I have no doubt you know which part of a dipole to elevate to satisfy your needs and keep you happily contented.

I am also happy with grounded verticals with which many people insist (not me) most of the radiation occurs from that part of the antenna which is nearest to the ground.

I have not contradicted myself. Please read more carefully. But on this later occasion you did snap at the trailing worm. No damage was caused. I am an animal lover and don't use barbed hooks. ;o)

What all this has to do with what parts of an antenna do or do not radiate remains a mystery to me.

Yours, Reg.

Try looking up an elemetary book on antennas and launching of radio waves.
There's usually a diagram showing the electric lines of force surrounding a
dipole. I wouldn't be surprised if there is such a diagram in an ARRL
publication. If there isn't one then there ought to be. Technical editors
please note.

As I mentioned, it only requires four or five "why?" to stump modern science. An infinitely long sequence of "why?" (even just eight) is a sure-fire sign of a religious argument.

Sure, I've seen that a thousand times. I just don't get the bit about the collapsing field racing back to find the screen door has already slammed shut (so to speak, er, write). I didn't know it was a timing issue. I don't recall reading about that little detail before.

All the antenna books that I have easy access to, and I've got a shelf full (ARRL, RSGB, physics), are a bit weak on answering these sorts of basic fundamentals. I'll double check though. Thanks.

Go to your Home Depot store or electrical supply store and get a tube of Nomax (sp??) compound. It is used to connect aluminum wire to copper and eliminates the corrosion problem you will have otherwise.

Steve

Hi Jeff,

Haven't the foggiest. This was 5-10 years ago when my buddy's
bloodhound group passed through various public service bands. Getting
new equipment did not seem to be a problem. They usually operated
mobile and would set up a cross band repeater in a position to match
the coverage area. Getting into the grant cycle is most successful if
you can offer a service to an emergency agency. You have to attract
their attention and find a white knight that can usher you through the
maze.

It's a good idea also to install a tinned copper washer between them.

I do a lot of programming, just not C++. my forte' is bash scripting and
firewalls (and perl language scripting/programming).

btw, what compiler are you using? if its something thats C++ capable, you
already have half the battle won.

I do have linpsk working here finally (had to edit the makefile to
account for some changes in where the shared libs are kept).

in any case, I'll look forward to seeing a linux version of this program
at some point.

Hi Tom,

Backwards? With respect to what, when? Would it help to say his
style is Ironic?

The American response back then was a little more direct:
"We might be more willing to enter upon the imperial task if our
British cousins were not so outspoken in their eagerness to get us
to do so. Their willingness to have us share the glory of
civilizing the Orient awakens a suspicion that the glory is not
altogether a profitable one. Great Britain evidently has more than
she can carry and would like to divide the glory with us.
...
The pursuit of imperialism has raised up antagonists to Great
Britain in every part of the world; it has imposed upon her people
a heavy burden of debt and taxation; it has disturbed her politics
by the continual menace of war and thus prevented the
accomplishment of many needed reforms at home; and finally it has
brought her into a position where without an ally she is

confronted by a hostile world and is in danger of having her commerce, and perhaps even her empire, swept away at the first outbreak of war.

Rightly considered the white man's burden is to set and keep his own house in order. It is not required of him to upset the brown man's house under pretense of reform and then whip him into subjugation whenever he revolts at the treatment."

Things haven't improved much since whoever is singing the song....

Right, I think people are reading more
into my question than intended.
Whatever the status of the source,
its deflecting the wattmeter to 150W.

Now for another question:
To recap, we have a transmitter>jumper>wattmeter>feedline>load
typical 50ohm ham 2m setup lets say. The wattmeter (bird 43 for example)
reads 150W forward and 50 reflected.

How much power is dissipated by the load?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-04 05:15:05 UTC
From: gaschafer@attbi.com
Message-ID: <3ded8fa2.8514381@netnews.attbi.com>
Source record: 130048

I think the key words in the original question were "shoe string
budget".

Yes I do understand ctcss very well. I made no comment about it as
there is little he can do
about the problem and it sounded like he understood it also as he
mentioned that they had the
interference when at the top of the mountain.

Even putting a simple repeater on VHF channels may not be a simple
task. There are very few
"repeater pairs" available on VHF. It may be possible to obtain them
under "special emergency"
allocations if the volunteer group would even be qualified. At that
point I would assume he
would be consulting with "professionals"

It is difficult to diagnose the whole problem sitting behind the
computer and not seeing the whole
picture.

My suggestion of looking at the antenna as a partial solution seemed
like it may be the easiest
(and read cheapest) thing to start with. It alone may solve most of
the problem in at least being
able to communicate with somebody.

And yes upside down ground plane antennas do in fact work. A ground
plane has a takeoff
angle that is tilted up compared to a vertical dipole. So mounting it
upside down does give some
down tilt to the signal. Is this guaranteed to solve his problem? It
may help and it may not help.
Depending what is there now for an antenna. Of course there are
commercial gain antennas
available with down tilt that may perform better. But certainly not
for the "shoe string budget".

The help you may get from a "real professional" may be less than what
little I gave. I know from
first hand experience what some so called professionals do to solve
problems. Some do a good
job and some do a very poor job. I have helped many of them out with
antenna and combining
problems professionally. So I hope that my volunteer help is not too
far off base.

been there many times... The new OS X is a bsd sty;e kernel and appears
to be a bit more stable. still, I wonder just how much of a nitch market
apple (mac) still holds at times.

>
> You failed to mention UNIX, OS/2, (I hesitate to offer CP/M) and so on

> machine - not in commercial service.
well, actually, take a good look at IBM. they are doing the same thing
for linux now that they did when the computer revolution first kicked off
in the late 1970's. Then, it was open-sourcing hardware that got the ball
rolling for the home computer market. today, its the adoption of
open-source that is fueling the current innovations in server
architectures and enterprise management. Mind you, I use linux as a
matter of course for adaptive technologies (everytime I have ever tried
to get winblows to work with either a speech or braille interface, it has
failed with drastic results, yet linux just keeps chugging).

I do remember cp/m (god, am I THAT old???) and it was a good OS for its day. However, market share can be measured by any on 100 or so criteria (having worked in telemarketing, one gets a real education on how demographics can be measured).

>
> The answer is to write applications in a Network Language (not an OS
> language) like Java.
Thats a good interrim solution, but it may not work on all platforms (there are still holes in most OS support structures that may prevent such things from working correctly). still, there is the point where its not possible to have a program work everywhere.

Hi Roy,

I guess I am one of those guilty ones in regards to skin depth
definition.

What would the current distribution look like in material that was
just one skin depth thick?

Thanks
Gary K4FMX

3819. 1/4 vertical versus 1/2 dipole questions

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-04 05:52:08 UTC
From: adam.white@sbcglobal.net
Message-ID: <3ded8fa1.560967789@news.sbcglobal.net>
Source record: 129970

I recently passed my General exam and so am just getting into DXing. My first priority is to establish communications with my brother who is on a sailboat off the Florida coast right now. He ranges between the Gulf of Mexico, the Caribbean, and the East Coast. I'm in a suburb of Fort Worth, Texas so that makes a distance of between 500 and 1500 (or so) nautical miles between us. I have an Icom 706MIIG and I'm trying to set up an inexpensive antenna in my back yard that will work for the purpose stated above. I'd appreciate any thoughts on the following series of questions ...

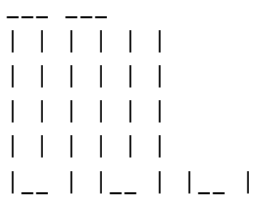
I have a 1/2 wavelength dipole for 20 meters made from #14 copper wire and using a Balun. I used it successfully at my prior home, but I have not yet mounted it at my new home. In fact, I'm evaluating possible locations now. Do you think I'll have better performance with it mounted 20' high with only 50' of (coax) feedline -- or a location 30' high which requires 100' of feedline? Assuming I get good performance from either of these locations, wonder how successful I'll be in general making contact on a daily basis with someone who is, say, 1000 miles distant?

Also, how much effect would a large (60' tall by 40' diameter dripline) american elm tree have if it was located 60' away from the dipole and in-line with my desired tranmission direction?

Assuming I have a reasonable SWR on 20 meters, there's no reason for me to use an antenna tuner, right? But even so, could I use that same wire WITH an antenna tuner to succesfully work other bands?

My last question is a little more complex ... This house has a patio area that is about 30' square. At ground level the decking is made from 2" * 6" boards. The area is also covered by a "roof" made of 2" * 10" boards. These roof boards are not laid adjacently, edge-to-edge. Their edges WOULD touch, if they were flat (i.e., parallel with the ground) but instead they are set on edge at an angle of about 45 degrees from the ground so that the sunlight goes through the boards in the morning but not in the afternoon (picture a venitian blind parallel with the ground, with the shutters part-way open). Here's the interesting part about this structure: on top of the roof boards there is a piece of steel cable roughly #14 (to help hold them down during windy conditions, I guess). It starts just east of the NW corner the roof and parallels the West edge for 30' all the way to the South end. There it takes a 90 degree turn to the East and runs about 4 feet. Then it takes a 90 degree turn back to the north, paralleling the first "leg." It runs all the way back to the North edge, turns 90 degrees east for 4', then turns south again. It continues "snaking"

in this fashion until it covers the whole area. There are six north-south "legs" paralleling each other, seperated by 4 or 5' between each leg. The cable is one continuous length. And the roof is about 10 above the ground. Viewed from above it would look something like:



OK ... so with that in mind ... I wonder if I can either use that wire (or a part thereof) as an antenna all by itself or else maybe use it as a counterpoise for a 1/4 wavelength vertical? On the latter subject , my understanding from the ARRL antenna book is that one can build a 1/4 wavelength vertical by raising the vertical radiating wire straight up 1/4 wavelength high. Then place a number of radials each 1/4 wavelength long beneath the vertical. So ... do you think I could raise my 1/4 wavelength antenna above this patio roof and then use incorporate the cabling into my radials? Would this improve the performance of the antenna? Could I use ONLY the existing cable as the counterpose, maybe adding only 4 radials (one to each corner)? If I lay the radials on top of the existing cable, would I connect them where they cross? Given my narrow objectives at present, I'm just trying to figure out the cheapest and quickest solution.

Thanks for your time.

100 watts plus or minus 5% of full scale minus the losses in the tuner and coax.

This is becoming overbalanced by half.

For practical answers to theoretical angst, the "Reference Data for
Radio Engineers" often cuts to the heart of the matter:
"The thickness of the conductor is assume to be several
(PERHAPS at least three) times the skin depth."

What remains is the standard usage of 1/e.

Hi Ironhead,
if two antennas are for the same band, optimum separation is achieved
at least at 10*wavelength distance ... a mile for the top band :-(If
they are for different bands (as in your case), they can be much
closer. Put them as far as possible and reasonable in practice.

a rambler? those are pretty much all metal. not good for an antenna to be

close to that. you might try a short whip with a load (like slapping an 8 foot firestick antenna on the end of a short run of pole or wire.

Richard,

That's a very interesting visual image, if you mean an iterative
mathematical process applied to marketing.

If you're alluding to the commercial activities here on the
newsgroup ("disruptive technology!"), it's a very bizarre picture.

Source record: 129971

Adam,
Since you already have a 20 meter dipole why
not put it up and see how things go. I don't
think there would be a noticeable difference in
signal because of a difference of 50 feet of feed
line, so try either/both locations for the dipole.
As for using a 1/4 wave vertical and the cable
above your patio, it would probably work. Until
you try it, I don't think anyone can tell you if
it will work well or not, or better than the dipole,
or not. Sort of a definite 'maybe'.
There's nothing that says that you can't change
your antenna at some later date, so try out different
locations etc. (Clear all this with your 'significant-
other', of course!)
You should only use a tuner if a tuner is required.
If you don't need to, there's no particularly good
reason to do so. If you have a decent match without
a tuner, don't use one. If you're going to try to use
the 20 meter dipole for other bands, you will have to use
a tuner, or some other means of matching impedance's. It
can certainly be done, but the results aren't always what
you'd want them to be. Another one of those 'try it and
see' things.
Good luck and have fun...
'Doc

I concur with Doc's comments. Doubtful you need to worry at all about trees or buildings unless your antenna comes in contact with one or more of them (NOT good). People tend to worry too much about the "small stuff" like this but experience will show most of it is relatively immaterial.

I'm a dedicated vertical user myself, and at 1,000 miles usually have better signals on a vertical. HOWEVER... a good vertical installation with a good radial system under it is 20 times the work of installing a good dipole and the difference I would expect is maybe one or two S-units at best.

Unless it just doesn't work for you, I'd stick to the dipole for now. Go for the closer, lower location. There probably won't be any noticeable difference from height, so why spend the extra bucks on another 50' of feed line or the effort to deal with the feed line where it won't be in your way?

Good luck... Ed, W5EJ

Dick:

I've ordered a W9INN remote balun, and will try to use that in combination with a minimum length of coax. Am going to try to get the outboard end of the antenna up a bit higher (off the trees), too, but have yet to figure out precisely how.

I guess this beautiful Johnson Matchbox will go unused a while longer....

Go with the greater height. 100 feet of coax at 20M is no big deal, so long
as you use decent coax. LMR240 works great, and it is 1/4 inch.
>
> Also, how much effect would a large (60' tall by 40' diameter

The elm is a complete NOOP. I live essentially in a woods of 80-100 foot
oak and tulip trees, and they cause no problem with a tribander at 40 feet.
Duce Island came back to me on the third call. Why not put the antenna up on
the elm?
>
> Assuming I have a reasonable SWR on 20 meters, there's no reason for

You might want to consider 40M in addition to 20. Maybe 2 dipoles at a
common feed point, but it would take some pruning. You would have to adjust
the 40 M first. I have 40, 17, and 12 M off the same feedline up about 60
feet. I do not own an antenna tuner.

[snip]

Yep everyone is correct!

100 Watts out of the transmitter, 100 Watts [minus small losses] into the
load, and...

Ba da bum...

that so called "reflected power" must then be just a fiction!

Why the hell do we need "reflected power"

And... in the words of the imortal Jackie Gleason... "away we go!"

Benson,

The wavelengths are so long here, that you might not want to bother with the coax, so long as the radio is grounded, as through the power plug, or better, a ground connection to a cold water pipe. The coax will reduce noise pickup from the house, but will act as a capacitor to ground. With a 50 foot of antenna, your SWR at 1000KHz will be about 100:1. Without coax, the whole wire , starting at the back of the 920, will be part of the antenna.

From: "Peter O. Brackett" <ab4bc@ix.netcom.com>
Message-ID: <asl7lo$4d$1@slb6.atl.mindspring.net>
Source record: 129984

Disruptive Technologies indeed!

There are imany examples of disruptive technolgoies which were widely celebrated by the lay public, I list but a few which might be so considered, along with the names of their revered inventors.

The invention of the steam engine [Watt] was, the invention of the telegraph [S. F. B Morse] was, the perfection of wireless was [earned amateur radio operator Guglielmo Marconi a Nobel Prize], the invention of the triode vacuum tube [Lee DeForest] was, the invention of selective filter networks [Campbell] was, the invention of FM [Major Edwin Armstrong] was, the invention of the transistor [Shockley, Bardeen & Britain] was, the discovery of the mathematical formula for channel capacity [Shannon] was, the invention of the integrated circuit [Jack Kilby, Robert Noyce] was, the invention of the Yagi-Uda antenna was... etc...

The important thing to note here is that none [None!] of these protaganists were known as unabashed self-promoters, sensation seekers or were ever found to be "reckless with the truth". Some, perhaps Armstrong from the above list, were not to enjoy their fame in their own lifetim.] but all were eventually recognized by the lay press and the lay public and widely celebrated as the inventors of disruptive technologies.

But fractal antennas, disruptive?

An interesting approach to linear loading, but not disruptive, perhaps the fractal geometry disrupts the continuity of their elements, but...

Where are the earthshaking news stories? The calls for knighthood, the Nobel Prizes, etc...

What???

All get here on this august USENET NG is boyish boasting and often unsubstatiated and somtimes outlandish claims from Dr. Cohen, with no earnest attempt to place any of the work on fractal geometry antennas [by anybody] in perspective.

Disruptive indeed. tsk tsk tsk... for shame Dr. Cohen how dare you to attempt to include yourself in the Pantheon of the Greats of electro-technology!

From the responses to his overtures for praise and validation on this NG it seems that Dr. Cohen is not revered but reviled.

Why?

Could it be that one of the main attributes of disruptive technologies is that they stand on their own and need no promotion by their inventors?

It seems that Dr. Cohen simply can't wait! Dr. Cohen seems to indicate that *he* should be placed in the august company of those listed in the Pantheon above, yet he can't seem to meet the basic requirment to be so honored. Patience and acceptance.

It seems more likely that *he* is the single most disruptive thing about antennas which utilize a fractal geometry, not the so-called technology itself.

It's really very sad, since the public awareness of any small benefits achieved in niche applications by utilizing a fractal geometry for antenna design have probably now been completely washed away by the useless controversy generated by Dr. Cohen's selfish impatient self-promotion.

Disruptive technology indeed!

Using coax, most of your power on the other bands would be dissipated
as heat in the coax. I use a 33 ft. dipole, resonant on 20m, to work
all bands 20m-10m. I feed it with 300 ohm ladder-line and vary the
length of the feedline to achieve a match without a tuner.

What you need is a diagram of the electric lines of force (the near field) around a dipole, including the lines of force which have become detached because of their movement, have closed upon themselves and are expanding outwards into space. (The radiation field).

It's so simple I'm sure you have already visualised what occurs.You just enjoy interminable discussions. ;o)

Source record: 129990

"For more than 100 years advantage has been taken of the fact that 3-phase transmission lines, for the same weight of copper and support, have a significantly lower energy loss than 2-wire lines."

I think you are confused, three phase distribution is used to minimize the capital investment of hardware for a given power requirement.

This has no application to amateur radio where the power levels are in the kilowatt range. To get lower loss just use better transmission line and keep your VSWR unity..

[snip]

Heh, heh... now that sounds like a lot of bafflegab to the uninitiated!

It's really pretty simple I think, here's I Smac's setup...

radio>jumper>wattmeter>coax>load
^ ^
100W 100W

100Watts supplied from the radio, 100Watts delivered into the load, and...

Ba da bum...

50Watts of "Reflected Power" held in the wattmeter for later use in case
it's needed
to supply power to the computer calculating the SWR?

What?

Message-ID: <Xns92DA67A18BEAmichalkunyahoocom@128.233.3.7>
Source record: 129992

Does anyone know or made an antenna switch that could be used by the winradio plugin? It's controlled by a com or lpt ports.

It is more in how it stops the oxidation. It isnt just grease. The oxidation is caused by galvanic action between the two dissimilar metals. The paste contains a compound of metals in such a proportion that the effect is eliminated.

The new connection will conduct just fine to ground. It is when galvanic action leads to corrosion, that you end up with high resistance, and thus, lousy ground. Quite a few homes burned to the ground when alluminum wire was introduced into home electrical systems (Usually the oven or clothes dryer feed). After the connections corroded and went high resistance, they cooked until they ignited adjacent materials. Prevent the galvanic action, prevent the corrosion, maintain the good continuity path to ground.

Actually, FM might be considered disruptive. I've had some fun mulling this one while I have been testing some 900 MHz-2.4 GHz antennas (about 2/3 of an inch in size).

The Yankee Network does seem to have qualified as a niche market, which RCA ignored as not of interest.

I'm reasonably well educated on Armstrong's and Hammond's patents and backgrounds (among others), so this fact seems to have escaped my middle aged memory.

Roy, Not 'understanding' is not all that unusual.In San Diego they
have a
the 'University for American English' which is vastly different from
the
'English" that is used thru out the world. So there was no need to say
'sorry' because I also was guilty of the same offense. Why else wou;ld
I go thu all that explanation of detailing my silly antenna which
normally brings forth derision if I also didn't "mis-understand' the
intent of your post.
My children by the way, write and speak American English tho they do
often
lapse into "proper English" when they wish to attract the opposite
sex.
Regards
Art

Written like a true old, cold warrior. Here's another Kipling quote, a
fragment
from a poem called "The Young British Soldier."

When you're wounded and left on Afghanistan's plains,
And the women come out to cut up what remains,
Jest roll to your rifle and blow out your brains,
An' go to your Gawd like a soldier.

Thanks to you who have already responded to my questions! One additional thought that has just occurred to me: the *easiest* place for me to mount that dipole would be right on top of the 30' by 30' patio area. In a matter of about 5 minutes I could erect three wooden supports -- one at opposite corners and one in the middle -- on the flat "roof" of the patio. If those supports extended, say, 5 feet above the roof then my dipole would be 15 feet above ground. That's lower than optimum, but it would ve extremely secure and easy to reach / modify. Since that's so easy I think I'll try it first. So here's my belated question: that cable I described which is on top of the patio would now be only 5 feet below the dipole. There would be no direct contact, but what if any effect would the cable have? If it's likely to be negligible then I'll proceed with this plan first (the patio is closer to my house and would require even less feed line than either of the other two potential dipole locations I mentioned).

Adam

3862. built-in SWR meter effectiveness

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-04 17:11:26 UTC
From: adam.white@sbcglobal.net
Message-ID: <3dee33ab.602966159@news.dallas.sbcglobal.net>
Source record: 130006

I have a fairly new (2001) Icom 706MKIIG which includes a built-in SWR meter. I've previously used this meter to tune a 20m dipole and it seemed to work satisfactorally for that. I'm just curious, though, whether the built-in SWR meter is as effective as a stand-alone SWR meter? I'm about to call Icom and ask this question, but thought I'd ask it here, too -- to get an unbiased answer!

I'm about to do some experimenting with various antenna types and locations. So I wonder if I need to invest the $$$ in a separate SWR meter. Would be nice NOT to, but I'm not sure how accurate the built-in meter might be.

Thanks,
Adam

Hi Bill,

No, it is a simple life's lesson illustrated by Jobs when he returned to Apple (to revitalize it) and immediately killed Franklin (the major clone builder that threatened to overtake Apple in sales) by muttering that oath "IP."

At the other end of the processing spectrum, Microsoft for more than 15 years showed a steady climb in stock value until it hit the Justice Department and the threat to split the dinosaur in two (or more). The world held its breath for nearly three years (and the stock stagnated like a cesspool) to a wishy-washy resolution. With the decision handed down the stock was then free to do what was natural as a consequence - it remains stagnant.

This illustrates at least three companies that just don't get it when it comes to capitalism: ego driven and investor screwed - fractal marketing at its best: if you are personally doing good, **** the rest.

As an operational suggestion. And this will help you in keeping in touch with your brother. Check into the Intercon or Maritime mobile net. It operates 24/7 all day long on 14.300 mhz. Just give it a listen and follow the proceedure. Nothing too it really. Just holler in when net control askes for it and list your traffic . I.E. this is so and so would like to call so and so. Go from there. Nice helpful fellows.

Have fun and enjoy.

Hi OM,

Sure, how much is another matter, and if it matters is another matter.

You probably will have to re-tune it (at the antenna or in the shack).
Then again, maybe not. Either way, when tuned, measure its bandwidth
and if it is significantly wider than published figures (at your
height) then the tree has become a linear loading element: some C, a
little L, and perhaps a significant R.

How significant? Well, one fractal developer optimized a tree by
driving a nail into it (that was the only contribution of wire), and
then driving the nail with RF. It worked! But how well was never
revealed (optimization was for the benefit of the designer, not the
reviewers).

So, your plight falls somewhere in between nearly perfect, and nearly
fractal. Your good fortune is in having not optimized with a
disruptive technology. ;-)

Nope, 50 watts of reflected joules/sec interfering with 150 watts of
forward joules/sec to cause the impedance transformation represented
by an SWR circle of 3.73:1 on the Smith Chart. The reflected energy
is being used for impedance transformation and therefore cannot be
used for any other purpose. How can I break you from trying to use
the same energy for two different purposes? Do you try to use the
same energy for powering your computer as you do for drying your
clothes?

If you calculate the time it takes for the generated wave to reach
the load you can calculate exactly how many joules of energy are stored
in the reflected wave. For instance, if the transmission line is 100
nanoseconds long, there will be 5 microjoules of energy associated with
the 50 joules/sec of reflected power. There will be 15 microjoules of
energy associated with the 150 joules/sec of forward power. If the
system were flat (matched), there would be only 100 microjoules of
energy stored in the transmission line.

It's all explained on my web page under "W5DXP's No-Tuner All-HF-Band
Antenna". I use knife switches to select a binary length continuously
variable in one foot increments from zero to 31 ft.

You probably won't notice the difference. It may slightly
alter the radiation pattern and common mode currents.
Depending on spacing and power, the end in the tree may
arc since that is the highest voltage section on 40m.

I believe I recall that there was a second-order problem, as well.

Copper and aluminum have significantly different coefficients of
thermal expansion (aluminum's is a third higher). This means that as
a copper/aluminum junction heats and cools, the two conductors will
tend to "work" against one another. The thermal changes cause
physical stress on the junction, which can thus loosen the junction,
increasing the resistance, causing more heating, causing more
stress... poof.

> Prevent the galvanic action,
>prevent the corrosion, maintain the good continuity path to ground.

Yup. Fortunately, ground wiring shouldn't be handling significant
currents on a continuous basis, and so it won't be as subject to
thermal-expansion stress.

I've seen specialized "pigtails" which are intended to be
pressure-crimped onto the ends of aluminum wires... the ends of the
pigtails can then be connected safely to "copper wire only" outlets
and etc. I imagine that the design of the pigtail is such that it
resists both galvanic corrosion (either via choice of alloy, or via
use of the right kind of anti-corrosion paste?), and thermal stress
(by using a strong, ductile alloy with a suitable coefficient of
expansion?).

Normally, when using windows, the windows media player should handle
this automatically.
If it doesn't, that usually means it's not the "selected" player to play

stuff pulled off the browser. If the files don't auto load, then you will need to d/l the files and manually play them in a player. Media player, quicktime, real audio, or even the windows sound recorder can play them. The original files were 44k wav files. Just the first file was nearly 8 megs. I compressed and converted to the mpegs using the windows sound recorder. In my windows setup, windows media player plays the files no matter which browser I use. My 706 is run to my sound card here in the house. Makes it very easy to record. Was direct, so no mike coloration. What you hear is what I hear, except that it's better here in the full fidelity. I listen in psuedo stereo through two large speakers. Actually, I was surprised at the quality of the 11k-2 mpegs.. Not too bad audio quality considering how small it crunched down the files. Note that I used stations that were not overly strong or clear channels. Thats the true test...Pulling semi weak ones out of the muck...If I listen to a loud clear channel, it sounds much better. MK

Ok I know this will sound dumb, but!! Why not just go BUY a short peice of Copper grounding wire? The length needed. It seems like a better long term solution, and would be the more correct way of making the connection anyway?? No??

Instead of investing time and money in compounds, and bi-metal grounding clamps!! Just a though!

3876. Re: built-in SWR meter effectiveness

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-04 21:29:35 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <asls3t$91e$1@helle.btinternet.com>
Source record: 130015

Hi Adam, don't bother calling Icom. They'll consider it to be a nuisance call. ;o)

You could call an SWR meter salesman who will try to sell you one.

Accuracy? - don't make me laugh!

A so-called SWR "meter" built into the transmitter is a much more practical instrument than an add-on instrument. It informs the operator exactly what he needs to know. No more and no less. That is why equipment designers specify it should be placed in the same box as near as possible to the transmitter.

The SWR meter, located in its usual position, does not in fact measure SWR. It merely INDICATES, nevertheless very importantly, whether or not the transmitter is connected to its designed-for load resistance.

This is usually 50 ohms and the "meter" itself must also be designed for use in a 50 ohms system. A built-in "meter" guarantees it has been designed for use with the transmitter it is immediately connected to. The two will have been adjusted to match each other in the factory.

A more appropriate and far less misleading name is the TLI = Transmitter Loading Indicator.

The TLI indicates the transmitter is correctly loaded when the "measured SWR" = 1:1 But the term SWR is meaningless because there is no significant length of line between transmitter and "meter" on which a standing wave can exist.

(Note 1: A true SWR measurement can be obtained only by TWO independent voltage (or current) measurements on a transmission line SPACED APART by 1/4-wavelength. SWR means exactly what it says. It is just a ratio of two different voltage measurements. A meter located at one point cannot determine SWR. Furthermore SWR is independent of the Zo impedance of the line on which the SWR is determined. The two 1/4-wave spaced points at which the voltage measurements are made correspond to the maximum and minimum voltages which may exist at different places along a line.)

(Note 2: But it should be stated, SWR is an important parameter in the analysis of transmission lines. But the line must at least exist before an analysis becomes meaningful. At HF, a few inches of wire between transmitter and so-called meter does not qualify.)

I shall now take refuge in my well-stocked, deep, bomb shelter.

Not all of that 100W (minus small losses) will be transferred to the load
unless the load is matched to the transmission line impedance and purely
resistive- reactances don't absorb power.

> Ba da bum...
>
> that so called "reflected power" must then be just a fiction!

and the bit that isn't transferred to the load is reflected back down the
line as refelcted power.

Think of an analogy. Light is reflected from a window because the refactive
index air and glass differ. If you could made the glass with the same
refractive index as air you would get no reflection and all the light (less
abit lost in transmission) would pass through the glass.

The refractive indices of the air and glass correspond to the impedances of
the glass and air. The light reflected back is the reflected power.

>
> Why the hell do we need "reflected power"
>

So we can deduce the reflection coeff. and, by suitable calibration of a
meter scale, indicate the VSWR or just SWR.

Now there is a Brit who denies SWR exists but we don't take him seriously.

|Not all of that 100W (minus small losses) will be transferred to the load
|unless the load is matched to the transmission line impedance and purely
|resistive- reactances don't absorb power.

You obviously haven't been following along. The reflected power has
already been accounted for. The net forward power is 100 W. All of
it is dissipated in the load.

Furthermore, "matched to the transmission line impedance and purely
resistive" are mutually exclusive when the line has loss.

A slightly reactive load can present a better match to a reactive
transmission line (i.e. one that has loss) than does a load that is a
pure resistance. So, a purely resistive load *is not* the optimum
load for a lossy line.

> Regards from Reg G4FGQ

Here's a verbo-visual image that I wonder if it would be correct? If we were to slow things down from say 14 MHz to maybe one hertz or less and could shoot out a single cycle of energy, we would start by seeing the forward needle rise to 100 while the reverse slowly barely lifts from zero. Then we would see the forward needle drop back towards zero (but not all the way unless it was a directional coupler type of circuit) while the reverse crept up to 50. Note particularly that the forward meter hasn't reached zero before the reflected meter starts indicating power....the time delay being simply based on the length of the line. Then the process would be repeated but on the second cycle there would be an increase in the forward indication because the reflected wave is hitting a who-knows-what match at the xmtr output and bounces back in the forward direction.
So logically there is more than the original 100 'watts' reading that was seen on the first cycle. I'll let the math pros have at it because I think this second cycle 'forward' reading gets rather complicated. There is the xmtr out, minus the feedline loss to the load, the amount of reflected voltage due to the mismatch, feedline loss again, then another (possibly unknown) amount of reflected voltage seen at the xmtr output terminal...then its phase relationship with the actual transmitted signal.
The third cycle has all of that plus more...and so on.

The point is that a reading of 150 watts forward and 50 reflected doesn't simply indicate a 'real' output power of 100 watts. It may be pretty close but I suspect there's enough 'if factors' to keep it from being a rule-o-thumb. Based on the same thought, the '50 watts reflected' isn't going to be particularly accurate either after the first cycle.
Maybe there IS a rule-of-thumb that can be applied and possibly it will in fact approach the simplified 150-50=100 once this process has been repeated 14 million+ times in a second.

So yes, time is obviously a factor. Each repeated cycle will increase the voltages read but after a few cycles the voltage addition rules make

it moot since the succesive increases are so small....so its pretty easy to ignore 'time' at 14 Mhz unless one goes back to extract the behaviour of a single cycle or two, in which case, apples are being compared to oranges.

My 2 centavos.

-Bill WX4A/KP4

Brian, there you go again, unnecessarily complicating and confusing matters.

Regardless of line and load impedances, all power leaving the generator must
be dissipated in load. There is nowhere else for the stuff to go.

> are more on the civilized side.

No, there is no real difference at all. If anything, I can think of
places much more dangerous. I'd rather walk at night in Houstons high
risk areas, than I would say in LA, or Detroit, etc. There are crooks
no matter where you go. I could be out in the sticks all by myself,
and be in more danger than here in the big city. All it takes is one
crook on the prowl to ruin your day. Many of the crooks out in the
sticks are worse than the ones in the city. No nearby cops around to
ruin their day. It's when I'm out in the sticks by myself that I feel
the most need to have a gun. I never carry a gun in Houston. I did
keep a gun at a few businesses I worked at or owned though. The threat
of robbery is real around here. But no worse than any other big city.
Houston is very modern. It's not like many people think looking at the
cowboy movies. I've gone out on the west coast to LA, and SF, etc.
Those cities are very "old" and sorta run down looking compared to
Houston. When I got back to Houston, it looked like it was built a
couple of weeks ago, and someone is constantly vacuuming the streets..
Much cleaner and more modern than LA. Houston is probably one of the
most "modern" cities in the country.

> them, anyway. I was always after bigger and bigger road signs.
> Have you ever shot up a road sign, Mark? Don't lie.

Oh, I'm sure I've taken shots at a few, but I've never shredded one.
My shooting skills? I used to use a pellet gun to shoot locusts laying
on the branches of trees 30-40 ft up, in trees. All you see is a small
bump on the tree branch. I used to cut them in half. I also used to be
able to shoot flying bumble bees and shoot them in half. I liked to
target shoot, and kill beer cans , etc. I used to hunt quite a bit
when I was young, but I've kind of grown out of that I guess. I don't
really like to kill stuff anymore, because animals are a limited
resource, and getting squeezed out the picture more every day. I would
kill a deer if I wanted the meat, but I'm too lazy to clean and
process it, etc, so I just leave em alone. I will still make a mess
out of a rat or other similar varmit though. I used to shoot them off

the power lines at dusk when they start their nightly prowl. Lots of rats in Houston. Even river oaks has loads of them...MK

3892. Re: 1/4 vertical versus 1/2 dipole questions

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-04 23:17:03 UTC
From: 'Doc <w5lz@cwis.net>
Message-ID: <3DEE8CEF.9139BBAD@cwis.net>
Source record: 129931

Adam,
I'm not so sure that the cable over the patio wouldn't
affect the dipole, depends on the length of the cable to
an extent.
I really wouldn't worry about the losses in the coax too
much. A 100 foot feed line at 20 meters of almost any coax,
should work just fine. Giving away the extra height by
mounting the dipole over the patio would have more affect
that the feed line losses.
Moving the antenna further from your house also has the
benifit of helping with any RFI you may have. Antennas closer
to the electical devices in your house tend to cause RFI.
As I said before, try various places and ways of putting
up your dipole. You don't have to make it 'permanent' to start
with.
'Doc

Bill:

You are getting very close to a deep understanding of power matching.

It's interesting that you let the frequency go to very low values like
1.0Hz.

OK... now mext let the frequency continue downward from 1Hz towards zero Hz,
go in log
steps, say 0.1Hz, then 0.01Hz, then 0.001Hz until finally in the limit you
reach 0.0Hz.

Now at DC (0.0Hz) does VSWR mean anything?

Is there any reflected power in the system at DC?

What does conjugate match at DC mean?

Will the SWR meter still work at DC?

If not, then what is the magic frequency [fm = magic frequency] below which
all reflections stop and VSWR becomes meaningless and why?

Food for thought. If a theory/visualization of reflection dynamics is to be
valid, then it must be valid for all regimes, from DC up to the highest
frequencies, otherwise it is invalid.

Think about it...

> be dissipated in load. There is nowhere else for the stuff to go.

Well maybe not in your set up as you claim to have no transmission lines.

However, most people do and all have losses. A 3dB feeder loss means 1/2 the power never even gets to the load, any reflected power is also attenuated by 3dB before being bounced back again by toward the load. That is why you can use a long length of coax as a dummy load- even if it is unterminated- in that case nothing gets dissipated in the load it all does in the line.

Try a worked example: 10W from the tx to a line with 3dB loss to a 25 ohm load (all in a 50 ohm system)

Forward line loss is 5W, 2.5W goes 'into' load, and 2.5W is reflected. Of the 2.5W reflected 1.25W is lost in the line on the return journey.

Even ignoring any more reflections (at the tx back to the load) the line is dissipating 6.25W and the load 2.5W and there is only 1.25W to 'share' on future trips. That power seems to have found somewhere else to go other than the load.

Out of curiosity, which type of generator (perfect or Thevinin) do you assume in your 'analysis' ? I suspect that is where you are going wrong.

Reg, you call the SWR meter a TLI if you want but you do the hobby (esp. newcomers) no favours by your ill thought out ideas.

I think you had better check your references before you start slinging
around business school bafflegab as well
as scientific bafflegab. Moving to a new academic domain will not allow you
to escape scrutiny and questioning.

I wonder did you attend HBS or are you just a casual reader of HBR?

I checked all of my back issues of HBR and I believe your attribution for
the terminology "Disruptive
Technologies" is incorrect, it was in fact Arthur Porter who originated the
terminology.

The way I see it, AC is AC no matter how you slice it. It won't ever be
DC. There is a distinct dividing line between the two even if you get
down into the cycles-per-century scale.
Of course then again, the 'time' context matters in such a case to
distinguish the two. Same as it does in visualizing SWR.

Yup, your right. Sounds dumb. Then have your copper wire to aluminum antenna connection up 40 foot in the air where it is easy to service on cold rainy freezing days.

You use aluminum wire down from the antenna so the connection most likely to need servicing is within reach.

Take care Brian, Reg actually knows how SWR meters work, he as an excellent program on his site explains the internal circuit and workings of those venerable
and mis-named devices and he has a free program on his site that will help you to
design your own TLI/VSWR meter. Check it out.

It's all really very simple here's the full details in the one neat mathematical equation emulated by
most every so-called "[V]SWR meter ~ B = V - RI:

V is the "actual voltage" across the load impedance Z.
I is the "actual current" passing through the load impedance Z.

Z = V/I ~ The unknown impedance, |V/I| is the magnitude of Z, and theta = arctan(Im[Z]/Re[Z]) is the phase angle of Z.
R ~ The "arbitrary" reference impedance. Most use R = 50 Ohms resistive, but it could be anything depending upon
what you wanted to do with your meter.

A = V + RI ~ The ficticious forward voltage, calculated by the "internal" analog computer in the VSWR meter.
B = V - RI ~ The ficticious reflected voltage, calculated by the "internal" analog computer in the VSWR meter.

P = V*I cos(theta) is the "actual real power" dissipated in the real part of the load impedance Z.

When V = RI then the TLI indicates that B = 0 and the load is "matched".

What could be simpler. The TLI a concept whose time has come.

No reflected power needed!

"Reg Edwards"
> You just enjoy interminable discussions. ;o)

Not at all. What you see is what I am - hidden motives usually pretty close to zero. Since this is the world famous r.r.a.a NG, then why not discuss the basics of EM radiation ?

My concern (not quite the right word) was about your description of the mechanism of radiation depending upon the collapsing field. This doesn't feel right.

For example, if a battery is connected to a solenoid, then an EM wave will be developed and will radiate - **even if the battery is not disconnected** (until tomorrow afternoon). The sharp rising edge step function can be applied electronically to avoid arcing.

The radiation can be detected on an AM radio across the room. If the solenoid and battery are 'Mad Science' large, then you can 'fry' the AM radio across the room and any other solid state electronics in the area. Perhaps this is a near field effect, but this 'signal' will certainly radiate into the far field.

Remember, **the field doesn't collapse** until tomorrow afternoon.

The process of EM radiation *obviously* does not 'depend upon' collapsing fields.

Elucidation welcome.

I don't seem to recall making any claim on who came up with that moniker.

But, like virtually all the statements you have made of late, they are designed to make me look foolish, with the intent to discredit. They have no basis in fact.

For example: your statement regarding almost all the technologies you listed indicates you do not seem to be aware what a disruptive technology is.

The standard reference regarding disruptive technologies is Professor Christensen's book:"The Innovator's Dillemma". Thus my allusion.

My wife (HBS '87) and I have a signed copy. I imagine that the 4 other HBS folks I work closely with also own copies, based upon our lively discussions of the matter.

I'd enjoy looking at the HBS article you allude to. Could you kindly provide a reference? Also, can you cite links or references which support your assertion (of being 'disruptive') on the various technologies you listed?

If the cable in inline with the antenna wire, it could effect the
tuning. If the cable is at right angles, it probably will have little
effect. BTW, I vote for the dipole for 20m use over the vertical. The
vertical might make a good "2nd" antenna, but I doubt it will beat the
dipole on medium paths. Maybe even the longer paths. Even a fairly
low dipole "20-30 ft high" is high enough off the ground in terms of
wavelength to work pretty well. You should have no problem working
anyone as long as the band cdx are ok. Also, if I were to run a
vertical on 20m, it would not be a ground mount. I would use an
elevated ground plane, or 1/2 or 5/8 wave vertical. Even a storebought
compromise R7 or R8 will likely beat a ground mount unless it's got
half a zillion radials under it for 20m use. It's my opinion that
verticals should never be ground mounted. I consider it about as smart
as ground mounting a dipole. The only reason I don't complain about
it on the low bands, is you usually have no choice. On the higher
bands, this is not the case. Myself, 20 meters and above, I would
NEVER, EVER, run a ground mount vertical. But thats just me...I ran a
full size 5/8 ground plane at 36 ft on 17m. "Doubled as a 1/4 wave GP
on 40m". On 17m, that antenna beat all my other ones including the
dipoles. But if it were ground mounted, it would have been a dud I
bet. MK

> ask it here, too -- to get an unbiased answer!

Sure it is. That one reason why I have preferred icom mobile rigs in
the past. I didn't have to drag around an extra SWR meter with me.
Many of the older kenwood mobiles had no built in meter... In one
sense, I consider it better than an outboard meter. Why? Common mode
currents , varying feedline lengths, etc can skew an outboard meter
and cause it to read slightly different than the one in the radio. But
what the radio sees is what matters the most as far as power foldback.
If the radio's meter shows a good match, as far as the radio is
concerned, it should be. No use in having a 2nd opinion unless you
just like to watch meters. It's plenty accurate enough for gov work. I
have a 2nd meter in my tuner, and use it because it's a big and easy
to see dual needle meter, but mobile or portable, I use the one in the
rig. I have a mk2g and the meter seems to work fine to me. It's also
auto setting, so you don't have to calibrate for varying power levels.

Oh I'm aware of Reg's work.

Problem is that the theory isn't exactly new and I get irked when someone rehashes an old idea and just ends up confusing things. Reg used to post in one of the uk groups but stopped when his 'new' theories were 'uncovered'.

We have enough problems with people knocking our new licensees (the Foundation Licensees, like the old US Novice) the last thing you need is someone confusing the technical stuff they are learning!

Usually we are able to interrupt electricity more abruptly than we can start it. Reactance slows electrical rise. That is why radiation is most often larger from opening a contact than from closing it.

National Electrical Code, if it applies where you live, doesn't allow
aluminum ground wire within 18" of the ground. You would need to use a
10' ground rod driven 8' to comply. DON'T solder any ground connection!
This is also a code violation and safety hazard. Any lighting strike
will melt the solder and you'll lose your ground when you need it most.
You also need to connect the new ground rod to your service ground. This
will prevent a difference in ground potential between the two systems
which could become a shock hazard. This is also a code requirement.
Best solution would be a #6 copper ground wire attached to antenna mast
using an AL/CU lug bolted to the mast. Use NOALOX on the back of the lug
to help with the oxidation. Coating of silicon caulk over the connection
wouldn't hurt.
Copper will also stay tighter in the lug and won't break as easy as the
aluminum from the wind vibrations in your antenna.
Hope this helps.

Reasonable, but use Nicopress and you never need service a splice or tap regardless of metals joined.

Search on "Nicopress". Nicopress sleeves are applied with such force that moisture is excluded and thermal expansion can`t loosen the grip on the metals joined.

My point is that radiation DOES occur, and I haven't disconnected the battery yet. The field hasn't collapsed, and yet radiation has occurred. Ergo ipso facto SPQR RSVP CQDX - the argument that radiation depends upon field collapse can't be the whole story.

By the way, that very same inductance slows electrical fall by exactly the same mechanism. That's why there is a spark as you try to interupt the current. The spark would cause "extra" radiation. That's why I specified an electronic switch - to avoid the distraction of the spark and its radiation.

Hi everyone,

I don't know much about antenna, but I just learned how to increase the power output of my home network wireless access point from 30mW to 100mW. The hack works great, and now my access point does to. A very noticeable performance increase.

I'm wondering how concerned I should be with a device in the corner of my living room outputting 100mW 24 hrs a day. I think I remember reading that RF danger is not only power, but the frequency.

Should I be concerned?

J. Harvey wrote:
"I didn`t know it (radiation) was a timing issue."

As electrical charge and current change, their resulting fields change. A field is the effect exerted through a distance. Iron is attracted in a magnetic field. Paper is attracted in an electric field. These effects appear at a distance with the speed of light or somewhat more slowly.

A changing magnetic field creates a changing electric field. A changing electric field creates a changing magnetic field.

So, as these fields race away in space, they regenerate each other. The rub is that in a vacuum there is nothing to conduct a current.

It was Maxwell who speculated that displacement (the kind of current that flows in the non-conductive space between capacitor plates) current generates a magnetic field the same as conduction current does. Radiation in space requires no conduction, only displacement current. Maxwell was right. Hertz proved Maxwell correct.

Self-induction happens in the near field from the energy closest to the radiator, but some energy is far enough removed in distance and phase to be uninvolved in self induction and it gets away as fugitive energy in space. That`s how radiation happens. The energy is flip flopping between the electric and magnetic fields.

Best regards, Richard Harrison, KB5WZI

Software patch to the A/P's firmware?

>The hack works great, and now my access point does to. A very noticeable
>performance increase.

Tripling the power would give you about an 80% increase in range
(assuming a fairly simplistic model on how the signal is propagating).

Most of the inexpensive consumer-grade cards and access points seem to
be rated for about 15 dBm of power (30 milliwatts)... the
Cisco/Aironet models can be cranked up to 20 dBm (100 mW) as a
supported feature.

>I'm wondering how concerned I should be with a device in the corner of my
>living room outputting 100mW 24 hrs a day. I think I remember reading that
>RF danger is not only power, but the frequency.

Proximity is a big issue, also, and also duty cycle.

The FCC regulations which cover 802.11b operation allow a "point to
multipoint" device such as an A/P or PCMCIA card to transmit at power
levels of up to 4 watts effective radiated power (isotropic). Since
most such devices have antennas with a few dB of directional gain, a
more usual (equivalent) standard is 1 watt of power delivered into a 6
dBi antenna.

Even hopped up as it is, your access point is transmitting only a
tenth of the legally-permitted power, and you're probably sitting at a
good distance from it.

It's worth remembering that the transmit duty cycle of an 802.11b
access point is generally pretty low. When not in active use, it's
sending out a short "beacon" packet 10 times per second, and is idle
the rest of the time... the duty cycle isn't over a few percent, which
means that the average power is only a few milliwatts.

You're likely receiving as much, or more RF exposure on a day-to-day
basis from the 802.11b card in your laptop (or whatever) - even though
you use it for relatively brief periods, you're a lot closer to it.

A 2.4GHz wireless camera/video-sender product probably transmits a
similar amount of power (15 dBm or so), but with a duty cycle of 100%.
If you've got one of these in your house you're already exceeding the

802.11b RF levels by quite a bit.

Microwave ovens also operate in this band (most commonly) and their shielding is far from perfect... 802.11b LANs and video senders tend to suffer from significant interference whenever a microwave oven is turned on. If you use a microwave regularly, this could quite well expose you to more total energy in the 2.4GHz ISM band than your access point does.

So, my guess is that you probably haven't increased your RF exposure level enough to matter.

You probably _have_ increased your _legal_ exposure by a very small amount, in that your mod to the AP has probably voided its Part 97 FCC certification.

If you end up causing interference with other users of the 2.4 GHz ISM band (which would include licensed amateur radio operators working the 13 cm ham band), it'd be your legal responsibility to shut down, un-hack the A/P, rearrange your antenna, install tin-foil drapes, or do whatever else was necessary to eliminate the interference.

It seems very unlikely to me, though, that anyone would ever make an issue of this.

Please do make sure that you've enabled proper security on your access point (WEP, MAC-address restrictions, "stealthing" of the network ID, etc.), so that you don't find neighbors, drive-by spammers, etc. making use of your Internet connection and your home LAN without your knowledge and approval.

Try the acceleration of charge as a cause of radiation. Feynman writes about
it
in his _Lectures On Physics_ available in book stores everywhere. Of course,
if you
know that accelerating charge causes radiation then you might ask what causes
the
charge to accelerate. You'll probably have more fun asking this question on a
physics newsgroup. There is a large contingent of resident crackpots writing
to
such groups and the answers are liable to be more entertaining than what you'll

get here.

Bill, WX4A/KP4 wrote:
"My dos centavos."

The Bird wattmeter takes a sample of voltage across the coax and the current in the coax. It scales the two samples to equal quantities.

The incident wave has voltage and current in-phase. The reflected wave has voltage and current 180-degrees out-of-phase.

Thus the reflected wave samples cancel with the slug pointed to measure forward power.

In the reverse power direction, polarity of the voltage and current samples are inverted. So the forward power samples cancel and the reverse power samples add in-phase and register on the meter.

The idea is simple and workes well due to craftsmanship and calibration.

My two cents.

No, there is no real difference at all

Sure there's a difference, Mark. In Texas, as in other places with concealed carry laws, the owlhoots aren't the only ones carrying, and don't think the baddies don't know it. Or soon find out. As someone said, where anyone is likely to be packing heat people are *very* polite to each other.

I have a brother who lives in Texas who told me not long ago, as we discussed this subject, that there was a recent case where a hoodlum showed up in a restaurant and stuck a gun in the cashier's face, whereupon TWO patrons stood up and plugged him. Don't think you'll see that on the Left coast. And you'll see it far less often in Texas in the future, too. They do eventually get the word.

None of this is new stuff either. I recall from the mid-80's when I took a call from a state trooper saying he
was detaining a van load of illegal Mexican aliens at roadside. He requested I contact INS at Kansas City for
instructions on their disposal. The reply from INS: "Turn them loose". Which is exactly what we did.

> Try the acceleration of charge as a cause of radiation.

Exactly. Acceleration of charges. Physics 101. Been there, done that (and more). I agree with all that. (Did anyone think that I didn't ??? Geesh...)

Now compare and contrast the conventional view (acceleration of charges) with Reg's description. (This is the point where I jumped in and started asking questions.)

"Reg Edwards"
> Energy becomes detached from the near-field with
> increasing distance from the antenna because the
> near-field doesn't have sufficient time to fully
> collapse back upon itself during the radio-frequency
> cycle. The field velocity is restricted to that of light.
> The energy detached gets lost in space and changes
> its name to Far Field.

A perfectly fair extract of the above is: "(EM radiation occurs) because the near-field doesn't have sufficient time to fully collapse..."

I'm confident that Reg knows his stuff (that's obvious in the long run), but I still don't like this description (above) of the cause of EM radiation. His description implies (heavily) that it depends upon ("because" of) a field collapse mechanism.

Appeal to basic symmetry (gut reaction to only including field collapse, but not expansion) indicates that the description probably isn't correct.

A quick gedanken (with a solenoid and a battery) proves it.

Oh well. Whatever... sigh...

|
|Oh I'm aware of Reg's work.
|
|Problem is that the theory isn't exactly new and I get irked when someone
|rehashes an old idea and just ends up confusing things. Reg used to post in
|one of the uk groups but stopped when his 'new' theories were 'uncovered'.
|
|We have enough problems with people knocking our new licensees (the
|Foundation Licensees, like the old US Novice) the last thing you need is
|someone confusing the technical stuff they are learning!

No fooling. Particularly when that someone is claiming that a 25 ohm
load in a 50 ohm system is reflecting half of the incident power.
(That someone is you by the way...)

"Try a worked example: 10W from the tx to a line with 3dB loss to a 25
ohm load (all in a 50 ohm system)

Forward line loss is 5W, 2.5W goes 'into' load, and 2.5W is
reflected."

Tsk tsk. Now tell Reg you're sorry.

Hi,
try ON4UN's "Low Band DXing", I think there is a chapter about
shortened beams (mainly for 40 and 80 m bands).

The best imported english beer that I have drank in Texas, was
Whitbread. Funny name, but pretty tasty beer.. Yep, Bass is pretty
ho-hum...I don't drink much anymore really. I used to like heineken
dark until they changed the recipe and pretty much ruined it. I guess
that was like 15?? years ago or so when they did that...Most american
lager beer tastes like chemical backwash, although many of the new
small U.S. "microbreweries" are catching up to EU standards pretty
fast. MK

> Gary K4FMX

I don't know the answer to that one right off. I have quite a good selection of references and texts, but they invariably make the assumption that the thickness of the material is at least several skin depths. I think it ends up being pretty academic -- in practice I think conductors of about one skin depth thick are regarded as being essentially transparent. This would be the case for a lot of conductors around the audio range. At RF, the assumption that all conductors are many skin depths thick is generally a good one. And in between, the interest is mostly in round conductors rather than flat material. The answer to your question can be calculated, although, like I said earlier, not on a pocket calculator -- it has to be done numerically. I haven't taken the time to write a program to do it, and a search of my references and the web didn't come up with the answer.

One clue comes from a table published by the NBS (now NIST) in 1912, for round conductors. According to the table, a round conductor with radius of one skin depth has an RF resistance that's 1.02 times the DC resistance. This says that the current density is essentially constant in the material. At two skin depths radius, the ratio of RF to DC resistance is 1.26. Interestingly, neither of these is very far off what you'd calculate if you assumed a constant density down to one skin depth, then zero density below that. This calculation gives 1.00 and 1.33 for one and two skin depths radius respectively, and is exactly correct if the material is infinitely thick, so it's interesting that it does so well at one or two skin depths.

So the short answer to your question is that -- I think -- the current is nearly the same on both sides of a conductor which is only one skin depth thick. But I haven't done the calculation to confirm this.

--

Hmmm... your wife an HBS graduate, well now this NG is really starting to look up, first yourself,
and now another Ivy Leaguer joins us here on this "rough and tumble" newsgroup. And a feminine
participant to boot. Her active participation can only represent an improvement over your own
testosterone charged out of control technology jock postings!

I, for one believe that we really need some feminine input here on this NG to moderate all the testosterone
flowing from the postings of the myriad technology jocks who keep piling *it* higher and higher.

In fact I would recommend that you introduce your dear wife to us all here and let her do all your posting
from now on.

I for one would welcome her with open arms, and I would ask that the other denziens of this NG be gentle
with her. Of course I cannot vouch for or control the behavior of any other than myself, and as you well
know, I am always the perfect gentleman. If your dear HBS wife can be persuaded to participate, that way
you can retire from the NG and take a rest from all of the harrasment and pursue your scientific ideals.

But...before we accept her postings without questions, we all have to know... what was her HBS GPA
and especially her grade on Prof. C's class?

Unfortunately, we were too poor, and I never got to attend an Ivy League school, I attended a one room
schoolhouse in Essex County, ON... the same one who graduated John Kenneth

Galbraith, and I had to
learn all this business stuff on my own, but then you'r "Paul Drake" has
probably already found out all of that.

BTW... re your dear wife. I'll bet she is not as "disruptive" as you!

What's her "handle"?

Call sign?

Happy Holidays,

It was easy. It appears that the radio a Linksys WAP11 is built to accept
the power increase, but Linksys "hides" the control to do so from you. There
is a good article on it here:
http://www.seattlewireless.net/index.cgi/Wap11Hack

That's what this was. I wonder it Linksys intended to use the same hardware
in a more expensive unit at some point.
My card is still a limiter, at 30 mW.

That's the 2nd time that you have mentioned that.
The 1st time was:

> An interesting and fortuitous mathematical oddity
> is that the effective resistance of a conductor many
> skin depths thick happens to be exactly the same
> as if the current density were constant with depth
> and equal to the surface density, but abruptly
> stopped at one skin depth.

That 'interesting and fortuitous mathematical oddity' is simply due to the definition of skin depth as being the point where the current falls to weird number 36.7879441...% (= 1/e); instead of a nice round number like 50%. That is all closely related to the very reason that they (Napier and Euler) discovered 'e'. In other words, the 'oddity' is actually tied into the basic meaning of 'e'.

Roy, I'll bet you knew that already. But I thought it was worth mentioning explicitly - for the benefit of lurkers.

Gary Schafer wrote:
"What would the current distribution look like in a material that was just one skin depth thick?"

A conductor carrying current is surrounded by an electromagnetic field distributed along its length. The conductor may be considered a guide for the field.

Consider a point along the conductor. There is some slowing of the wave in the conductor giving the electric field lines a forward tilt. In other words, these lines are not exactly perpendicular to the surface of the conductor. The conductor is a drag on the wave.

Magnetic lines are parallel to the surface of the conductor. They are also perpendicular to the electric field lines. The propagation direction is perpendicular for practical purposes to the wave consisting of electric and magnetic lines which are perpendicular to each other.

The voltage difference in the direction of wave travel is greater than that perpendicular to the conductor, which is being absorbed into the conductor.

The wave velocity slows as it sinks into the conductor where it encounters increasing opposition. Lenz says self inductance opposes current produced by the varying field. Ohm says resistance dissipates some of this same current.

Progressive retardation as the current sinks deeper into the conductor slows the current causing its phase to progressively lag behind the current at the surface. At some depth the phase lags the phase at the surface by 180-degrees, given sufficient material thickness. This means the current will reverse directions creating eddy currents.

A summation of current density throughout the conductor equals the current an ammeter would display if this could be done.

Current density decreases exponentially deeper below the surface. The depth at which current is decreased 1 neper is the skin depth, 1/e, 0.368, 8.686 db, or pick your own equivalent. I like 38.6% of the current density at the surface. That`s Terman`s characterization, so it`s good enough for me. This depth is the effective skin thickness. As Roy says, this assumes sufficient conductor thickness.
If you had a fat wire wih uniform current throughout its depth equal to the surface current down a depth equal to the skin depth, a hypothetical situation only, the power loss would be the same as the actual loss in the conductor. This is a convenience for calculations .

I`ve already given skin depth formulas and a table of depth versus frequency for copper in this thread. At low frequencies and normal wire sizes significant current flows in the middle of the wire. At r-f nearly all the current is at the surface.

A No. 36 AWG copper wire has a diameter of 0.005 inch. Pretty fine! Its radius is half that. Skin depth in copper at 1 MHz is 0.00260 or about equal to the radius of a No. 36 wire.

Since we usually employ conductors larger than a No. 36 wire, skin effect in copper is usually said to be complete for r-f.

Best regards, Richard Harrison, KB5WZI

>

Let me run it past you again- it wasn't 110% clear:

10W into line.
5W lost in line (lost =converted to heat)
of the OTHER 5 W (that gets to the load), 2.5 goes 'into' load, and 2.5W
is reflected.

Of that reflected 2.5W, 1.25 is lost and 1.25W will get back to tx output.
Now, do you know what happens next?

Incidentally, the SWR meter at the tx end would read about 1.1 due to the
line losses. Which is why you need to use the SWR meter with caution.

The example was chosen to illustrate that the power CAN 'go' elsewhere than
the load- in this case mostly into heating the coax.- not to justify the use
of the SWR meter.

In accordance with a first aspect of the present invention, there is provided a
transportation facilitation device including a circular rim, a bearing in which a hollow
cylindrical member is rotatable about a rod situated within the hollow cylindrical member,
and a series of connecting members connecting the circular rim with the hollow cylindrical
member to maintain the circular rim and the hollow cylindrical member in substantially
fixed relation, wherein the rod is positioned on an axis perpendicular to the plane of the
circular rim, and substantially central of the circular rim.

Abstract from John Keogh's successful 2001 application for an Australian patent
(Innovation Patent #2001100012) for the "Circular transportation facilitation device" aka
"wheel".

Funny taste in beer you have ;-)

When I last visited Ft Worth I was taken to a very nice country / golf club some miles of town (NE I think). They served Newcastle Brown Ale, but they served it cold. The barman was most insulted when I asked for a less chilled bottle. Even when my host explained that Geordies (as people from that part of England are known) are weaned on it and so knew how it should be drunk, he still thought I was most odd.

I quite like US beer- draught Mic esp. 'Bud' is a bit syrupy for my taste.

It is odd that many people un Europe rave about German and Belgium beer (which I like) but knock US beer and, to me, they are much the same.

Either way, there is more to the US than beer- wonderful country and people I can't wait to visit again.

Having a gun didn't help my wife's father who was gunned down in a robbery
in 1968. It also didn't do anything for the armored car guards who were
recently plugged in Oakland. You guys who feel more secure carrying a
piece of iron strapped under your arms or hanging from your hips ought to
realize that, in a shootout, all parties are likely to get ventilated.

> Now, do you know what happens next?
>
Assuming that the transmitter is properly matched to the load
impedance it is looking into (via a matchbox perhaps), the 1.25W gets
reflected back towards the load. My question is what happens if the
transmitter is not properly matched to the load impedance?

That's why transmission losses increase with SWR, the power is
subjected to the same loss multiple times as it travels up and down
the feedline. With the "typical" HF installation however the feed line
loss is not high enough for the SWR to make any significant difference
in total power transferred to the load. Many people mistakenly think
that 50% reflected power means only half the transmitter power gets
radiated by the load - the result being that we often worry way too
much about SWR.

|> load in a 50 ohm system is reflecting half of the incident power.
|> (That someone is you by the way...)
|>
|Don't you have reactance in the US?

Yes, but where is it in the example you pose?

You said:

|(Quote) Try a worked example: 10W from the tx to a line with
|3dB loss to a 25 ohm load (all in a 50 ohm system)

|Forward line loss is 5W, 2.5W goes 'into' load, and 2.5W is
|reflected. Of the 2.5W reflected 1.25W is lost in the line
|on the return journey. (End quote)

I don't see any mention of reactive loads in your proposition.

Let's forget the line loss for the moment and deal with the 5W you
claim are incident on the load:

A 25 ohm load in a 50 ohm system has a vswr of 2:1, reflection
coefficient of 0.333, or return loss of 9.5 dB.

This latter number says that only 11% (.55 W) of the incident power is
reflected, not the 50% (2.5W) that you claim.
|
|I thought it was the land of plenty.

It is, and plenty of people are trying to sneak in illegally to

If you are talking about the normal manual switches for antennas, they are really expensive. I'm talking about one that is connected to computers com or lpt port. Then It's possible to use a plugin to control which antenna is on or off.

On the other side of the coin the U.S. has been extremely lucky. The
ever increasong group of Islam followers in the U.S. have not formed
cells to combat
the assaults by Jews and Christians, even tho we force all to pay
taxes for use against Islam. In Illinois the State have just changed
tax dispersement rules so it can borrow a few million to send out for
the fight against Islam and for a Greater Israel Yet we have not had
the religeous ethnic clashes that occur elsewhere and in general they
appear to be good citizens despite the growing number of attacks. On
the other hand we are seeing mounting violence by those that come from
Christian countries !
So as was the question earlier......Is this Country nutty or what ?
Since the World knows where missiles are made is it unthinkable that
we will eventually see them in use here by visitors?
I suppose this can be classed as whining if we cry when it happens at
home.
Art

In the past, I've purchased so-called "printer-switches" used to switch between two or more printers on the lpt port. Check with your neighborhood computer-house -- they should have something in stock, or be able to order you something. I recall paying about $50 for such a switch, back in the late '80s.

All Hail Bush!

It should also be pointed out, it is usually the first one to pull the trigger that wins. I am sure the loser is glad to see (from on high) the prize is a ride on Sparky for five minutes. Given the high degree of arming in Texas, and the equally high degree of sending folks to the chamber; that argues an airtight case for the warm snuggly feeling of security. If you feel a little chill, we will light up another convict and things will be OK again.

It will no doubt grieve the sniper-huggers that
"Federal agents yesterday raided the Tacoma gun store that was the last legal stop for a rifle later used in a multistate crime spree linked to East Coast sniper suspect John Allen Muhammad.
...
"and sold 'off the books.'"
...
"There appears to be a large number of guns sold off the books..."

Duh, with 300 guns a year average going out the back door to satisfied customers, why would a criminal want to steal one? When the owner reports these missing items each year, does someone have to shoot a dozen people in Washington D.C. to make a connection for the Feds? Does Arthur Anderson do the books for the Feds' reporting system?

There's value for your tax dollar. The Right Whiner solution will be cut the tax, eliminate reporting, and start a sniper-welfare system so that they can draw their constitutionally protected weapon of choice from federal armories. That worked like a charm for years in Bosnia and Yugoslavia until Clinton stuck his nose into that. Now they can only glower at each other and vote - what a waste. Where's my nuke?

[I am sure Tom can recognize an Ironic style, some others might be uncharacteristically enthused to elect me president of the NRA - I would like to point them towards the president's reading program so that they could discover the errors of their ways.]

death to the terrorist scum and those who arm them,

Message-ID: <uuvagtc3phr2f1@corp.supernews.com>
Source record: 129897

If my assumptions are correct a reflected wave is partially dissipated by coax loss and partially radiated by the antenna (and other ohmic losses(OML)) and whatever isn't radiated returns to the tx less coax loss and OML to be reflected again and so on. Now assume we slow things down, instead of 14 mHz we have a cycle per minute and make the transmission line very long. At the receiving end I will detect the first cycle followed and I wonder if some time later I will detect the radiation of the reflected wave. If my explanation is not clear, I apologize and suggest that this might be similar to a ghost TV signal or receiving signals that take two paths. If this is the case what kind of instrument would be required to measure the time and amplitude difference and could you from this determine that senders mismatch remotely? Or have I smoke and inhaled?

The velocity factor in copper is about 1.385 X 10^-6. That is, the wave in copper travels at about 1/700,000 the speed that it does in air. That's "some slowing" indeed!

Message-ID: <f49c48db.0212051223.49c5d1c4@posting.google.com>
Source record: 129899

I'm looking to pick up the ARRL Antenna Book to learn more about how antennas work and possibly do some simple homemade antenna projects. My first project would probably be an 800MHz antenna for a scanner, but I have an interest in learning about all kinds of antennas (so I'm not looking just for instructions on how to do that specific project).

How much does it matter which edition of the book I get? The 19th ed. goes for $24-30 new, and I have seen older editions for under $10. The basic science doesn't seem to likely to change from edition to edition. So what is the real difference? I'm willing to pay for the newest edition if there's a good reason to do so; I just want to be sure I'm not throwing money away.

Thanks.

Source record: 129900

Yes, thank you, I did know that, but it's always good to have more information presented.

For those who are curious about the derivation of this relationship, it goes like this:

For an infinitely thick conductor (or, in practical terms, one that's at least several skin depths thick), the current density at any depth x = Js * e^(-x/delta) where

Js = the surface current density
x = the depth (distance from the surface)
delta = the skin depth

So the total current I = integral for delta = 0 to infinity of (Js * e^(-x/delta) dx).

The value of this integral is simply Js * delta, for the reasons J. points out. So the total current turns out to be simply the surface current density times the skin depth. This is why we can use a uniform current density down to the skin depth and abruptly stopping, and get the correct answer for the total current (or resistance) even though the density actually decays exponentially from the surface.

I might even mention the simplified calculation again from time to time -- anyone bored by it can ignore it. The reason I mention it often is that people who aren't too sure about what's going on might see the simplified calculation being done and incorrectly infer that the current distribution is really uniform to a skin depth. Which of course it's not.

Roy Lewallen, W7EL

Seems improbable. Aluminum heats up, it expands. If not allowed to
expand by the nicopress sleeve, the aluminum will flow. Then when
it cools down it will contract. However it will not "unflow" and so
little by little the amount of aluminum under compression will
diminish and the connection will loosen. How does the nicopress
sleeve prevent this? It seems as hard to prevent as the expansion
of water turning to ice.

yes, you could detect this reflection and re-reflection. this shows as a
ghost on a tv signal. on any other signal all you would need is an
oscilloscope or really fast field strength meter. from the ratio of the
amplitudes you could determine the product of the line loss (for a round
trip) and the reflection coefficient. from the time delay/2 you could get
the length of the line if you know the velocity factor.

As always, it depends on the boundary conditions. If the conducting slab is less than several skin depths thick you must simultaneously solve for the fields and currents inside the conductor, on both surfaces, and perhaps in the volume outside the conductor, along with satisfying the proscribed boundary conditions.

Here's a link to Kevin Schmidt's excellent web page describing skin effect. It's well worth reading the text, and carefully studying the animation even if you lack familiarity with the mathematical concepts and the notation used in the presentation. Be advised Kevin uses slightly different notation and units than most commonly used in engineering.

Sean,

I have the 19th edition, and another one that is about 25 years old. There are quite a few differences in my two editions, of course.

I don't think the basic theory content has changed much in recent years, but if you buy a recent used version, make sure you get the software disc that comes with it...there are some nice little applications that will come in handy. They may also be available elsewhere, but I don't know.

That's for damn sure, you are totally confused.

One more (hopefully the last) time. A 25-ohm load in a 50-ohm system
is a 2:1 VSWR. A 2:1 VSWR equals 9.5 dB return loss or 0.51 dB
mismatch loss. That means the reflected power at the load is 11% of
the incident power. It is *not* 50% of the incident power.

Eighty-nine percent (4.46 W) of the incident power is dissipated in
the load on the first trip. If you want to account for the 25% of the
11% reflected power that makes it back from the generator on the
second trip, be my guest. After all is said and done, 4.6 W is
gobbled up in the load.

|
|10W into line.
|5W lost in line (lost =converted to heat)
|of the OTHER 5 W (that gets to the load), 2.5 goes 'into' load, and 2.5W
|is reflected.

B.S.

|
|Of that reflected 2.5W, 1.25 is lost and 1.25W will get back to tx output.
|Now, do you know what happens next?

I do, but obviously you do not.

|
|Incidentally, the SWR meter at the tx end would read about 1.1 due to the
|line losses. Which is why you need to use the SWR meter with caution.

No, it will read 1.4:1. Which happens to equal 15.5 dB return loss
which is the 9.5 return loss of the load and two times the line
attenuation.

> least several skin depths thick), the current density at any depth x =
> Js * e^(-x/delta) where
>
> Js = the surface current density
> x = the depth (distance from the surface)
> delta = the skin depth

The equation given by Roy describes the _magnitude_ of the current density at a depth of x skin depths. The equation is useful for for calculating losses but cannot be used to determine the phase, which reverses every pi skin depths. The complex valued current density for good conductors is proportional to the factor e^(-(j+1) * x/delta), where j^2 = -1.

This expands to: e^(-j * x/delta) * e^(-x/delta). The second product term gives the magnitude of the conduction current density as a function of depth, and the first gives the phase. Notice that the phase rotates by pi radians every skin depth, and the direction of current flow is reverse that at the surface at depths between pi and 2*pi skin depths.

The propagation below the surface is that of a very heavily damped wave (-54.6 dB/wavelength) with a remarkably short wavelength of 2*pi skin depths.

Take a look at Kevin Schmidt's excellent derivation of skin effect in good conductors at:

Oh please!!! You've been watching too many westerns. I don't know
anyone here who just carries around guns on an everyday basis.

And according to the recent Goverment Guide compiled from FBI data,
the only city in Texas on a list of the 25 most dangerous US cities
was Dallas.

I currently live in Houston. I'm not a native Texan, nor are many of
the other Houstonians. Houston is perhaps the most diverse city in
this part of the country -- people come here from everywhere. I think
it is often forgotten by others that Houston is a large, international
port city just like Los Angeles, Miami, New York, or Seattle. And most
importantly, people here LIKE each other and are respectful of each
other for the most part. When was the last time you heard of race

riots in Houston, or any kind of riots or uprisings for that matter? Outsiders might stereotype Texans as rednecks, but I've actually found Houstonians and many other Texans to be quite civilized compared to many people in other areas of the country.

You might want to get yourself updated some... it's not the 1800's anymore.

Hi Bart,

In contrast to one assertion made here, this is obviously a matter of science (not to speak of math). One point of confusion appears to be an effort to force a very thin foil of conductor to both act as part of a transmission line (a la coax shield) and to allow free and unfettered radiation THROUGH the foil (like I said, the genesis of this was typically confusing with ambiguities, mixed messages and fuzzy goals).

If we discard that noise as immaterial, then it would be useful for you to perhaps give us an encapsulation of the math that would serve for a conductor, in this form factor (to reduce issues of sidedeness and linked fields) of less than one skin depth. A short answer like the attenuation in dB should suffice. Roy likened it to being transparent, but I find that unsatisfactory because all metals are transparent - to varying degrees correlated to thickness.

The one, obvious, killer to that dyn-o-mite application is that if it is a poor skin depth candidate, it must also be a poor conductor (most of the metalized mylars used to shield require a drain wire to actually carry the burden of current over the length of the shield).

Aghh! Yes, I know. To indicate that the power could be dissipated in other
places than the load- ie in the line. Which is why I didn't what to ignore
it. I usually find that ignoring something you are trying to demonstrate is
an unproductive approach.

I think you are arguing for arguing sake.

Bill, if you're impatient like me and want to try it before your order arrives you can make a choke balun from several turns of coax (8-10) coiled into a fairly tight bunch near the far end of the coax. Makes a pretty effective RF choke.

Actually, our understanding of the theory has changed, with the availability
of high speed computing. Several of the assumptions which had to be made in
early days due to inability to correctly model things such as lossy earth
have proven to be exactly backwards.

The second practical matter is that recent editions use materials which are
actually available now. A lot of stuff we used to use is getting diffcult
to find.

The point another answer makes about the software is very valid also.

|> Oh I have. It was you that first introducted the 3 dB line loss.
|>
|
|Aghh! Yes, I know. To indicate that the power could be dissipated in other
|places than the load- ie in the line. Which is why I didn't what to ignore
|it. I usually find that ignoring something you are trying to demonstrate is
|an unproductive approach.

But all you have done is inject another factor before you have grasped
the point made by all of the other correspondents, who actually
understand the original proposition.

I dare say almost all of the regular participants in this group
(r.r.a.a.) are completely aware of the effects of line loss and don't
need a lecture from you about it.
|
|
| I think you are arguing for arguing sake.

Quite the contrary. I am trying to get you to see and/or admit your
mistakes. It was you that stated, "...the last thing you need is
someone confusing the technical stuff they are learning!"

Here, for once, we are in total agreement.

Now, let me pose a simple question for you that requires no more than a yes or no answer:

In a 50 ohm system does a 25 +j0 load reflect 50% of the power incident on that load?

[ ] Yes

[ ] No

When we get this cleared up, we can move forward.

I've often wondered, why is talking on a cell phone all that different
from talking on a ham radio? Do hams have wrecks while talking on a
ham radio? Do hams have wrecks while talking on a cell phone?

One thing that has changed in the past few years - the ARRL doesn't
like conjugate matches any longer. :-)

Thanks everyone for taking the time to answer my question(s)
I wonder if anyone could point out the error in my thinking,
and hence the reason for my original post.

I will lessen the severity of the example to help focus my question:

I have a VHF FM radio deflecting a Bird wattmeter to 100W forward
and I observe 10W reflected. (radio>jumper>meter>feedline>load)

Coax losses aside, If 90W is produced by the source and 90W is dissipated
by the load, where does the 10W come from?

I'm having a problem with conservation of energy, and obviously
must be missing something.

Thanks,
Smac

>ham radio? Do hams have wrecks while talking on a cell phone?

Part of it, at least, is the issue of dialing. A lot of people use ordinary, compact handheld cellphones in their car. Making a call on one of these is difficult to do with one hand, and pretty much requires that you take your eyes off of the road for several seconds to dial. I read one letter lately from a guy who observed a cellphone driver slowing down in the middle of the freeway - the driver was "steering" with his elbows, had both hands on his phone (one to hold and one to punch buttons) and was looking at the phone rather than at the road.

SMS messaging is probably making matters even worse, since people are now getting into the habit of "reading their email" on a tiny screen at 65 MPH, or even trying to type out a reply while driving.

I suspect that hams _are_ at some increased additional risk when they talk on a mobile while driving... especially when operating the controls on the rig. However, the control mechanisms on a mobile are more likely to be designed to be operated while driving - larger, capable of being operated without being looked at (at least for the volume and squelch knobs), and there's a lot less "dialing" involved since most of us probably tend to have two or three favorite repeater channels pre-programmed on the rig, and don't try to key in frequencies manually while in motion.

I am considering using the antenna described by SM0VPO at
http://w1.859.telia.com/~u85920178/antennas/balcant1.htm and
and attaching this to one of the posts on my 10x10x6 dog kennel with
ground radials buried about 1" below the surface (actually I think the
square piping on the ground should help as well for a ground plane I
hope). I would think that this would be a good place as well because
it will be about 50-75 feet away from the house. Also installing a
remote antenna switch will allow me to select the band I want to use.

The overall length of the antenna described is about 17 feet. Should
I raise the antenna higher since it will be essentially a ground
mounted vertical?

Hi Cam,
Most hams are probably not afraid to drop the mike when necessary
while most people are too afraid to drop or not concentrate on that
cell phone and the oh so important person on the other end.

I talk in the mobile often and it never distracts me from my driving.
Of course I have seen one person on a cell holding the phone, the
wheel, the pad of paper and the pencil they were trying to write with!
Oh well.

Somewhere around the 14th or 15th Edition, then-editor Jerry Hall, K1TD, completely re-did the whole Antenna Book. He pulled out inaccurate stuff which had crept in over the years, and included a lot of new and accurate information. The Antenna Book about doubled in thickness when this was done, so you can pretty easily tell a pre-overhaul edition from an after-overhaul edition. Since then, corrections have been made to information found to be inaccurate or unclear, but the changes haven't been nearly as drastic. I do recommend that you get a recent version, but if you don't want to shell out the money for a new one (a tremendous bargain even at the new price), I highly recommend that you at least get one that was issued after Jerry's overhaul.

The 10 W was put into the line in the first few nanoseconds after you applied power. Let's take the extreme and easily analyzed case of a lossless half wavelength 50 ohm line that's open at the far end. You turn on your transmitter, and it doesn't immediately know that the line is open at the far end. It merrily dumps 100 watts into the line, which it can't tell from a 50 ohm resistor. On the line are 100 watts forward and zero reverse power. The voltage and current waves arrive at the far end and reflect, arriving back at the input after a round trip. There, they encounter the signal still being applied from the source, resulting a complete re-reflection at the input end of the line. At that moment, the apparent impedance seen by the source jumps from 50 ohms to infinity. (What it sees looks like another source producing exactly the same voltage as it is, so current flow from the source ceases.) The source quits putting any power into the line since it's now looking into an apparent open circuit, but the re-reflection provides exactly the same voltage and current for the forward wave that were formerly provided by the source. So the forward wave, initially generated by the source, is now being furnished entirely by the re-reflected reverse wave. On the line, you've got 100 watts forward and 100 watts reverse, forever (remembering that our line is lossless). If the line were 100 ns long (one way), the transmitter would have had to provide 100 watts for 200 ns, a total of 20 microjoules of energy, until the reflection got back after initially applying power. That's where the energy on the line came from. Any time after the line is charged (that is, after the initial reflection hits the source), we can disconnect the source without any effect on what's happening on the line. The 20 microjoules of energy is bouncing back and forth on the line, and a magical lossless directional wattmeter inserted anywhere along the line will read 100 watts forward and 100 watts reverse. If you put a 50 ohm load on one end of the line, you'd get 100 watts into the load for 200 ns as the line discharges. (That, incidentally, is exactly the way they used to make radar pulses, although it was DC rather than RF applied to the line. A thyratron was used as the switch to charge a line -- usually a lumped element substitute --, which was then discharged into a magnetron. The reflected wave turned the thyratron off.) If you put any other load with finite resistance on the end of the line, you'd still get 20 uJ out, but at a different rate (that is, less power for a longer time).

Smac`s Bird wattmeter manual says. "Power delivered to and dissipated in
a load is given by:
Watts into Load = Wf - Wr

So, 90W = 100W - 10W

Wf is the sum of 90W +10W = 100W
100W is the sum of the 90 watts being produced and consumed plus the 10
watts just circulating in the system. Were there zero loss in the coax,
the reflected 10W would only have to be supplied initially. The power
required to make up the loss incurred of each reflected power round trip
in the coax is probably too small to sense as separate from the load
power.

Your SWR is 1.9:1. Your load is accepting 90% of the incident power
and reflecting 10% of the incident power. The 10W is energy generated
by the source but not accepted by the load, i.e. the generator has
generated more power than has been accepted by the load. Those conditions
happen during the transient buildup to steady state.

If you want to visualize what happens, consider a one second long lossless
transmission line. After one second, the T-line contains 90 joules. After
two seconds, the T-line contains 99 joules, ... after 'n' seconds, the T-line
contains 110 joules at steady-state.

Its most likely not going 'into' the radio but instead being
re-reflected again in the forward direction...or a least a substantial
portion of it.

The SWR is only 1.9:1 and can be considered a reasonable match. My IC-756PRO
doesn't start folding back until the reflected power reaches about 15W.

The only guarantee that "equality" buys is that you at least have a chance, and
that the need will be less likely when the crooks know they don't automatically
have the upper hand. The statistics on this are clear- where privately owned guns

are common, violent crime is definitely less so. The crooks don't dare be so bold, and being cowards they really don't relish being ventilated themselves.

I agree with Mark - Packing a gun everywhere would be much too much of a burden and responsibility for most of us to want to keep up with on any continuous basis. No question about it, any weapon is a very demanding responsibility. But there are times and places one can't feel the least bit secure without one, for very good reasons.

We can wish it was a more perfect world and that such situations didn't exist. That won't make the baddies act nice. Yes, sometimes both parties get "ventilated". Can't say that's any worse than only one, since the "one" would have been the victim, and at least he was able to take out the perp too. Seen that happen already, to an offduty police officer who was the victim of a carjacking. Both he and the perp died. But the previous carjacking in that same city ended with the brutal execution murders of two college girls who were in the car. That's better? A third girl, shot and left for dead, survived to testify against the two perps. THEY got 'life' when they shoulda been fried. No doubt they'll be on the street again in a few years. Helps to have a "ethnic" jury.

Your choices are to submit to the likely drugcrazed robber/rapist/whatever, and hope against hope he won't decide to "leave no witnesses", common these days since it helps assure there will be no prosecution - or defend yourself.
Failure to defend oneself just doesn't make sense. Might as well let Al Queda do it to us, it all comes out the same.

So your saying that my radio produces 100W
and my load dissipates 90W ?

Your radio is actually producing the 100 watts measured as "forward power." The 10 watts "reflected power" is going back into the radio. Thus only 90 watts (i.e. 100-10) is being delivered to the feedline. Depending on the feedline loss, something less than this will be delivered to the load.

This is too much reflected power and you can potentially damage your radio. You need to match the impedance of the feedline+load to the impedance of your radio. Perhaps your antenna is too long or too short but either way you need to fix this.

I dunno, Rich, I've spent a couple months in Texas this year and so far I haven't seen anyone yet that I could tell was armed other than some cops. Wonder where all the guns are? The "wild west" it isn't. You suppose those people who are packing are actually doing sensible things with their hardware, and normalcy actually reigns superior to some of the places where the owlhoots know they have the upper hand?

Dick

Maybe a more realistic question would be "where any vehicle may contain a firearm.....". Actually my experience with Texas drivers is that they are more courteous that most. The almost have to be, the traffic is awful in the cities. If they weren't courteous one might sit for hours waiting to pull into traffic. As it is people routinely yield.

I have yet to see any place that has concealed carry law to have a problem with it. It just doesn't seem to happen. Most people have sufficient common sense, and with the "filters" in place to keep unstable people and crooks from getting the permits, the laws just don't cause problems.

No, it's not going back into the radio. It's bouncing back and forth in the line. My favorite example is a 141.4 volt RMS voltage source connected to an open circuited half wavelength line through a 50 ohm resistor. Within a few nanoseconds of turning the source on, there's 100 watts forward power and 100 watts reverse power in the line, the 50 ohm resistor dissipates nothing, and the current into and out of the source are zero; it neither furnishes nor dissipates power.

It's not reverse power that can damage a rig. What causes damage is operating into an impedance it's not designed for.

Let's suppose I connect my rig through a half wavelength of 450 ohm line to a 50 ohm resistive load. My rig sees 50 ohms, and is just as happy as it would be feeding a dummy load; it can't tell the difference.

But if the transmitter is putting out 100 watts, the forward power on the transmission line is about 278 watts and the reverse power is 178. The load is dissipating all 100 watts put out by the transmitter (we're assuming negligible line loss here).

So what does reflected power have to do with whether the transmitter is happy? It can't tell the difference between a dummy load, a 50 ohm transmission line with 100 watts forward and zero reverse power, or the 450 ohm line in the example, with 278 watts forward and 178 reverse.

Too lossy.

Its an inverted F design with insufficient height for good 900 Mhz performance.

Injection molding is not a good manufacturing engineering practice for S-band:-)

I have some really great fractalized inverted F's there Peter. Ready to buy in quantity?

Hi, Art, and all interested:

Get a reliable copy of the Koran, and read Sura 9, the 'crusade sura', in which, inter alii, the antagonism of Islam to all other religions is declared, all but Mohammedans excluded from Mecca and rites of pilgrimage, idolaters menaced with slavery a/o slaughter, war declared on Christians and Jews until they are humbled and pay tribute ...

This pastoral idyll was often read on the field, before battle.

September 11th is the anniversary of a major defeat of the Mohammedans, at the hands of the Christians, several centuries ago, when the Mohammedans were once again threatening to take over Europe by force of arms. IIRC, in July 1683, the Grand Vizier Kara Mustapha, led his Turkish troops to Vienna and laid siege against the city. On September 11, 1683, a decisive battle was fought before the city walls. After an initial setback, Poland's great military leader, and later king, John Sobieski, with his forces, stormed the enemy camp, and routed its army.

IMO, the date of the assault on the US was no accident. Saddam moved his 'announcement' up one day in the same vein of thought.

Just in case no one can cite you a good CB shop on your planned route you might want to try a Loves truckstop. Every Loves I've been in seems to have the equivalent of a fairsized CB shop in it, with radios, antennae, and accessories. I'm sure a roadtrip of the extent you've planned will take you by several of them.

No, during the transient buildup to steady-state, not all the power
produced by your transmitter makes it to the load. Standing waves
require a certain magnitude of extra energy. That amount of energy
is not available for any other purpose since it is being "used" to
achieve the steady-state standing wave status. Once steady-state has
been reached, the transmitter continues to output 90 watts, the load
continues to accept 90 watts, and a certain magnitude of energy is
"stored" in the transmission line. The higher the SWR, the greater
is the magnitude of energy needed to support the standing waves.

Source record: 129866

Practical in-line wattmeters such as the Bird are not quite as perfect as described below. The directivity spec on the wattmeter element(s) when its output is perfectly terminated in the Zo of the system (50 ohms, typ) is about 26dB -- an apparent ~1.1 VSWR.

So if the system termination itself has a 26dB return loss, the meter could read anything from 1.0000...VSWR (infinite return loss) to 1.152 VSWR (23dB return loss), rather than the true ~1.1 VSWR of the termination.

The reflected power wattmeter reading is the net result of the relative magnitudes and phases of the true reflected power mixing with what leaks across the imperfect sampling element from the forward power in the system.

R. Fry, CPBE

Smac wrote:
"So you`re saying my radio produces 100W and my load dissipates 90W?"

Bird says:
"Power delivered to AND dissipated in a load is given by:
Watts into Load = Wf - Wr"
In the case above:
90 watts = 100watts - 10 watts
The equation balances ok. This asumes coax loss can be neglected when it is very small.

Power delivered to the load is close enough to the power delivered by the transmitter. It`s 90W in the example given.

The 10W rejected by the load adds to the 90W produced by the transmitter on re-reflection at the transmitter output. This produces 100W of forward power.

On first reflection from the load, 10% of the forward power had its phase between volts and amps shifted by 180-degrees. On re-reflection at the transmitter output, this re-reflected power had its phase between volts and amps shifted by an additional 180-degrees. Phase shift now totals 360-degrees and the re-reflected power has its volts and amps back in-phase and it is merged with the newly emerging power from the transmitter to make up the 100W of forward power.

If the transmitter can only deliver a tiny bit of power over 90W, it may take several round trips of reflected power to eliminate the incremental power required to set up the circulating 10W of reflected power. But at over 100,000 miles per second, the build up to steady-state is faster than a blink of an eye.

10 watts of the total forward power is not currently being delivered by the transmitter. It was delivered by the transmitter, but some time ago. The transmitter is only delivering the 90 watts indicated by the difference between forward and reflected powers.

Best regards, Richard Harrison, KB5WZI

"Seems improbable (that dissimilar metals don`t loosen a Nicopress grip)."

Nicopress grips a steel screwdriver shank with a large aluminum alloy sleeve crimped-on as a handle before your eyes at trade shows as a gift to you to prove its permanence. Never heard of one losing its grip regardless of abuse. Mine is intact after decades.

I`ve erected countless shortwave broadcast antennas using thousands of Nicopress sleeves to clamp large copper and Copperweld cables, stranded and solid. Also used them on steel guy cables to support antenna curtains and radio towers. Never had a sleeve failure. Unrelated cable failures, maybe. Sleeves no.

Nicopress sleeves are also used on fiber ropes. Most aricraft control cables use them. All dissimilar metals and they are faultless.

Dear Brian,

Regardless of line and load impedances and what the swr meter may be reading, if the line is sensibly lossless then all the power output from the transmitter must be dissipated in the load. Where else is the power to go?

How can a professional possibly disagree with such a simple and obvious statement?

By George, I think you've got it!

What? No more *reflected power* sloshing back and forth longitudinally
along the line between the ends, just pure *stored energy* sloshing back
and forth transversally *across* the line between the distributed
capacitance
and inductance of the line, like in a tank circuit.

Neat, now we can do away with all of that re-reflection of power gobbledy
gook.

RE: Other (deep) threads here on this topic

Suggest that the list below outlines the main factors determining the ratio of forward and reflected power in any RF tx+antenna system.

A. The net, operating source impedance of the transmitter
B. The Zo of the transmission line to the antenna
C. The impedance match of the antenna to the transmission line
D. The attenuation of the transmission line at the operating frequency
E. The electrical length of the transmission line (i.e., its exact number of wavelengths)

Items D and E usually have little affect in HF amateur radio situations, but are important at VHF and above.

Two theoretical scenarios for an FM/TV broadcast station (my background)...

1. If item B = item C, then whatever transmitter power that is injected into the sending end of the transmission line surviving its loss is radiated. Power reflected from the antenna back into the line is zero, and the VSWR on the line is infinitely low. Items A and E are irrelevant for this consideration.

2. If item B does NOT equal item C, then the antenna will reflect power back to the source. Standing waves will occur on the transmission line.

a. If item A = item B, then the reflected power is totally absorbed by the transmitter.

b. If item A does NOT equal item B, then the reflected power from the antenna NOT absorbed by the transmitter will mix with the forward power being generated at that time by the transmitter. Therefore the net output power of the tx at that time will depend on the magnitudes and phases of the two (forward) waveforms. The phase of the re-reflected component at the tx will be largely a function of the electrical length of the transmission line to the antenna; the magnitude will be largely a function of the impedance matches at both ends of the line, and line loss.

Item 2b above is the (almost) universal practical case. Broadcast transmitter sources can have a return loss varying from <1dB for some tube amplifiers to ~20dB for some solid-state PAs.

Hopefully this adds something useful to the posts on this topic.

This thread is off topic and should be continued on another newsgroup if it's
continued at all. If people want to believe that a hot pistol next to their
skin
will preserve their lives, that's fine. Hopefully, they'll never find out any
different. The other myth, that allowing everyone to carry a concealed weapon
will make society safer is proved to be a lie every day in the poorer sections
of
large cities where there are lots of concealed weapons and also lots of
killings.
My own opinion is that gun laws won't decrease the murder rate much. In
China, people have found they can kill each other very efficiently with
dynamite and rat poison. However, the religious assumptions of some
groups, that universal gun ownership will decrease crime and safeguard
civil liberties are just that: dogma without any basis in fact.

|of forward and reflected power in any RF tx+antenna system.
|
|A. The net, operating source impedance of the transmitter

Let's pause here for a moment.

With a lossless line, the ratio of forward to reflected power is
uniquely determined by the mismatch between the line Zo and the load
Z. If the line has loss the ratio will vary, increasing with increased
distance from the load, however; the source impedance has nothing to
do with it.

|B. The Zo of the transmission line to the antenna
|C. The impedance match of the antenna to the transmission line
|D. The attenuation of the transmission line at the operating frequency
|E. The electrical length of the transmission line (i.e., its exact number
|of wavelengths)
|
|Items D and E usually have little affect in HF amateur radio situations, but
|are important at VHF and above.
|
|Two theoretical scenarios for an FM/TV broadcast station (my background)...
|
|1. If item B = item C, then whatever transmitter power that is injected
|into the sending end of the transmission line surviving its loss is
|radiated. Power reflected from the antenna back into the line is zero, and
|the VSWR on the line is infinitely low. Items A and E are irrelevant for
|this consideration.

A always is.

|
|2. If item B does NOT equal item C, then the antenna will reflect power
|back to the source. Standing waves will occur on the transmission line.

Correct.
|
| a. If item A = item B, then the reflected power is totally absorbed by
|the transmitter.

Correct.
|
| b. If item A does NOT equal item B, then the reflected power from the
|antenna NOT absorbed by the transmitter will mix with the forward power
|being generated at that time by the transmitter. Therefore the net output
|power of the tx at that time will depend on the magnitudes and phases of the
|two (forward) waveforms. The phase of the re-reflected component at the tx
|will be largely a function of the electrical length of the transmission line
|to the antenna; the magnitude will be largely a function of the impedance
|matches at both ends of the line, and line loss.

Which is a complicated way of saying that with a given load Z, the
load on the transmitter varies with line length. Thus, without
retuning, the transmitter output may vary as the line length changes.

But none of this affects the *ratio* of forward to reflected power.

|
|Item 2b above is the (almost) universal practical case. Broadcast
|transmitter sources can have a return loss varying from <1dB for some tube
|amplifiers to ~20dB for some solid-state PAs.
|
|Hopefully this adds something useful to the posts on this topic.

Have you read the posting I've made several times now, and included in my "food for thought" essays (ftp://eznec.com/pub/food_for_thought/), where I show a line with 100 watts forward power, 100 watts reverse power, and *no* dissipation in the transmitter's source resistor, even with a perfect match between the transmitter and the antenna? Any statement about the reverse power being absorbed or dissipated by the source resistance has got to be able to explain this. Please show how that example is explained by your statement (a).

Peter, you've got the energy in the wave confused with the carriers of the wave. Do water molecules move along with the ocean waves? No, but the energy in the ocean wave rides the water molecules sometimes from coast to coast. The water doesn't slosh back and forth but the waves travel back and forth. The water travels primarily up and down. Have you never overlooked a beach where the big waves were coming in and the small waves were going out transparent to each other? In a length of transmission line with constant Z0, the forward wave is transparent to the reflected wave.

It is impossible for forward and reflected waves to affect each other unless they encounter an impedance discontinuity where reflections and/or interference occurs. The energy in the wave crashing on the beach is being carried by water molecules that were there close to the beach all the time. Something just gave those molecules enough energy to retreat from your ankle level and then crash on your head.

If you are saying the electron carriers don't slosh back and forth, I would tend to agree with you. Electrons certainly travel much, much slower than the speed of light wave energy being carried by the electrons.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-06 19:59:48 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <uv20dlg6buhbb3@corp.supernews.com>
Source record: 129785

Wes, how do you resolve this with the example I've posted several times now where an open circuited line has 100 watts of forward power, 100 watts of reverse power, and no dissipation in the source resistance?

I also posted an example yesterday where a 100 watt transmitter feeds a 50 ohm load through a half wavelength of 450 ohm line, resulting in 278 watts forward and 178 watts reverse on the line. Yet the source dissipation is exactly the same if you replace the 450 ohm line with a 50 ohm line, with zero reflected power, or a line of any other impedance.

In neither of these cases is the reflected power absorbed by the load. So is it only absorbed by the load sometimes and not always? If only sometimes, what are the necessary conditions?

All the antenna switches I've seen -- from Alpha Delta and others -- are controlled by a manual switch. And because they are rated for high power, that's the reason for their higher cost.

You might check some of the military surplus dealers, but they usually charge an arm and a leg for anything good...

Or, maybe you can build something of your own...

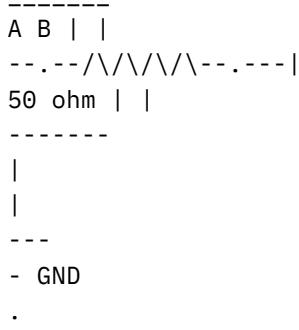
4048. Characterizing a commercial trap

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-06 20:05:41 UTC
From: nat.gurumoorthy@ubicom.com
Message-ID: <41325e56.0212061205.77307fca@posting.google.com>
Source record: 129786

I would like to characterize a commercial trap. Would the
following circuit work. A sine wave generator is hooked
up between A and Gnd. I use a 3 channel scope to monitor
Voltage between A-B B-GND and A-GND. The voltage drop
across the the 50 ohm will give me the current. Voltage
drop across the trap divided by the current gives me
|Z|. I can look at the phase shift to know if it is
Inductive or Cpacitive.
Questions: 1) Would this work?
2) Is there a simpler way to do it?
3) Are there any limitations to this method?
4) What are the possible error sources
to watch out for?



Regards
Nat AB6SJ

That test should give you reasonably good results, provided that A-B isn't a whole lot smaller than A or B. Even good scopes don't have very good common mode rejection in A-B mode, especially at high frequencies, unless you're using a scope or plugin specifically designed for differential measurements. So you'll probably need to increase the value of the series resistor quite a bit. Try with a few values and see if you get about the same results for Z.

Much thanks to Richard KF6KE, he had a line on aluminum in San Diego.

If you are looking for some, call:

Handy Metalmart
1540 McKinley Ave
National City, CA
619-474-3379

The stuff I got was 3/4 inch OD with 1/8 inch wall. Kinda' heavy for
antenna work, but OK for a single 10m dipole.

Message-ID: <%gaI9.8335$kz2.855117@newsread1.prod.itd.earthlink.net>
Source record: 129796

Got my aluminum for the 10m dipole, also got some RG8x.

I'm wondering if I should make a choke balun by winding about 7 turns of the coax near the antenna?

I read some on the web that say you shouldn't do that with RG8x, especially if you will be running more than 100w. I hope to do a max of 400w, and am now concerned about coiling the coax.

Do I need the balun for a single band 10m dipole, or should I just forget the balun?

Help is always appreciated...

In most jurisdictions, any person permitted to carry a firearm may be charged with public brandishment, criminal threatening, or even worse--should it become obvious to his (her) fellow citizens that he (she) is carrying. To walk as an armed citizen among fellow members of the public, one has a civil and moral obligation to keep the firearm concealed at all times--and a to know the law well--especially as it applies to defensive vs. offensive acts. In the US, odds are you'll never see anyone "carrying". Unlike those murerous cellphone thugs clogging our sidewalks and highways!

Stahr,
Winding a choke with RG-8x shouldn't be a problem, just
don't wind it too tight. If you force it into too small of
a diameter coil it could cause 'migration' (center conductor
moves toward the shield). A fairly 'loose' coil should work
fine.

A = B

Where:

A is a generator with a good source match (Zg). For example Richard
Fry's solid-state amplifier with 20 dB return loss. In transmitters
this is often accomplished by using quadrature couplers with the
fourth port port terminated in a matched load, or at microwave,
isolators (terminated circulators). Reflected power is "dumped" into
this load. (But you know that <g>)

B is a transmission line with Zo equal to Zg.

I can see where this is not the usual ham radio case and the source Z
can be different from the Z looking back into the source. It is
however, what I was envisioning Richard Fry meant. (Comes from too
many years in a labortory where good source match is a requirement for
making good measurements of VSWR.)

Wes

4063. Re: Forward/Reflected Power

Message-ID: <uv2l1948tlqu49@corp.supernews.com>
Source record: 129803

Ok, here's a case for consideration.

A = a generator consisting of a Thevenin source: a voltage source with a 50 ohm series resistor. This is a good model of a laboratory signal generator of the type used for HF measurements. I'll make the open circuit voltage 141.4 volts RMS, which is the voltage of the voltage source.

B = a lossless 50 ohm half wavelength transmission line.

This is, wouldn't you agree, a situation where there's a perfect match at the input to the cable?

First let's terminate the line with a 50 ohm load. The load will dissipate 100 watts. The reverse power on the line is zero. The dissipation in the source resistor is 100 watts. So here we have a situation where there's no reverse power, and the source resistor is dissipating 100 watts. The voltage source is producing the 200 watts being dissipated by the two resistors.

Now open circuit the line. We find that the forward power is still 100 watts. The reverse power is 100 watts. There is no load to dissipate power. The source is delivering no power. The source sees an open circuit. The dissipation in the source resistor is zero.

Now, here's a case where clearly there's a perfect match between the source and the transmission line. There's 100 watts of reverse power on the line. Yet the source resistor is dissipating nothing. At least for the simplest case I can think of, a Thevenin source driving a matched line, the reverse power clearly isn't being absorbed or dissipated by the source resistor. In fact, when the reverse power went from zero to 100 watts, the source resistor dissipation went from 100 watts to zero.

If you put an isolator between the source and the line, it's a somewhat different story. Then, the source sees 50 ohms even when the line is opened at the far end. Consequently, the voltage source continues to produce 200 watts of power. 100 watts is dissipated in the source resistor and 100 in the isolator termination. I suppose it would be fun for some folks to argue whether the 100 watts dissipated by the source resistor is reverse power, whether the 100 watts dissipated by the isolator termination is the reverse power, or whether both are simply the the power being produced by the source. In fact, when you disconnect the line altogether, there's no longer any reverse power. And the dissipation in the source resistor stays at 100 watts and the isolator resistor at 100 watts. This makes it difficult to justify the need for reverse power to produce dissipation in the isolator termination. A simple explanation based entirely on load resistance will suffice, and

it'll accurately predict the isolator termination dissipation regardless
of line impedance or the amount of reverse power on the line. For
example, if we connect the isolator to a 450 ohm half wavelength line
terminated in 50 ohms, we'll have 278 watts forward and 178 reverse on
the line, yet the isolator termination resistor will have zero
dissipation. This is easily explained if you entirely ignore the reverse
power and simply look at how the termination dissipation varies with
load impedance. That holds true for *any* kind of steady state source,
including an isolator or Thevenin source.

The notion that reverse power is absorbed or dissipated by the load is a
myth, based on misunderstanding of the phenomena involved. It's very
easy to provide any number of examples to show it's simply not true.

Jump start a down car battery from a good battery. There is little to no chance charge will flow from the lower charged battery into the battery with the higher charge.

Try to stuff the reflected wave back into the transmitter and you face a similar problem.

Best regards, Richard Harrison, KB5WZI

Assume that the jumper cables are really, really long - so long that their electrical length is comparable to the period of a normal 'jump start' (say about 1 minute). They are also perfectly lossless.

Assume (please - just for a minute) that 'launching' the boost down the cable is sufficient effort (a very, very low-Z set of jumper cables) that it significantly discharges the first battery. Obviously a rather wimpy little battery (almost like a capacitor); fully charged but very low amp-hours.

Assume that the guy with the dead battery suddenly decides to leave, taking his dead battery with him and leaving his end of the jumper cables disconnected.

So there is a significant pulse of DC traveling down the cable heading towards an open circuit. Obviously it will reflect and head back up towards the now-discharged source battery.

Will any of the energy go back inside the battery ? Will the recently discharged battery gat a little boost from its own former glory ?

I've twisted your 'jump start' example back around to something closer to RF. Apologies.

Steady state analysis need not apply - this is a transient event.

Obviously, if the source battery wasn't extremely wimpy, then...
...it's difficult to toss a bucket of water into a broken watermain.

Reg Edwards, G4FGQ wrote:
"---factors determining the ratio of forward and reflected power in any
RF tx + antenna system.
A. The net, operating source resistance of the transmitter."

"Is this a printing`s error?"

Must be.

Forward and reflected power RATIO, like SWR is affected only by the
mismatch between Zo and the load.

I have a Bird slide rule with an example:
"Set Reflected Power at Forward Power.
Example:
Pf = 5W
Pr = 1W
VSWR = 2.6
Return loss = 7.0 dB
Match Efficiency = 80%
Reflection Coefficient = 0.45"

Source impedance was not involved in any of the determinations above.
(The 5W was a given, as was the 1W.)

Best regards, Richard Harrison, KB5WZI

> Hi Dick,
>
> D'ya think all the killings were committed by bad manners?

Not at all, nearly all are committed by ex-convict previous offenders out on parole or otherwise set free by some bleeding heart. Most are multiple offenders who should be on ice permanently. Instead they're freed repeatedly to prey on the public, while citizens who insist on their right to self protection are assigned the blame!

OBTW, did you know that the US Supreme Court once ruled that the police have no duty to protect individuals, rather only the public as a whole? That ruling came after a case where a woman had been threatened and pleaded for police protection which was denied. She was killed, and her heirs sued the police, with that ruling resulting. Remember what the police did in the LA riots? They split, knowing they were outnumbered big time. It was "every man for himself", as it will be next time.

Not that it matters, we couldn't afford to pay the taxes required to keep us all in police protection. I worked with the police for 30 years and I can tell you that the main job of police is to deal with the aftermath. There are far too few of them to prevent much crime against individuals, it almost never happens. Their primary functions are to investigate and try to bring the perp to justice. Sorry about the victim, nothing we can do for him now.

Next someone will say "If we didn't have so many guns then the criminals couldn't get them either", making it necessary to remind seemingly sensible people that when we can't stop the importation of many tons of illegal substances our chances of stopping a black market in weaponry destined for the same criminal destination is slim to none. We haven't even began to address the sieve-like borders which allow all those millions of illegal aliens of every stripe virtually free access to our soil. I suppose since we're doing so good a job of keeping them out we can also keep them from bringing in firearms as they come, for sale illicitly as a ready source of cash. Right. Since the guns will be illegal the illegals won't bring them.
Got it. We also haven't addressed the tens of thousands of shipping containers coming into the country each and every day, UNINSPECTED. *One* of each ten thousand is actually opened and checked. Of course we can depend on no contraband coming inside those. Right. And just the other day our President signed an order allowing Mexican trucks to freely travel US highways, coast to coast. You suppose there's no problem there either? You really think any serious percentage will ever be checked on entry? US customs -the grunts on the line- will laugh at the very idea. They're much more overwhelmed than the police.

Anyone who thinks guns in the hands of criminals can be stopped by eliminating them from private ownership is a wildeyed dreamer, and unfortunately there are a lot of them around. All that can happen is for the average law abiding citizen to be branded an outlaw for owning his own protection - if we allow the clueless liberals to have their way with us. Does anyone REALLY believe that's the American way? Not in the America I live in. That means that some subversive element wants a change that isn't in the best interest of the individual citizen, under the guise of helping "protect" him. That sort of protection I don't need. My own is much more effective, in every way.

> killings.

Tom, looks like that pretty well describes your serious misapprehension of this entire subject. In those areas the people carrying all the concealed weapons are the very people who would be- and now are- legally banned from even owning or possessing them, much less carrying them concealed. Most are now armed illegally since there are almost universally laws prohibiting gun ownership by felons, as well as for possessing firearms with intent to use them to violate the law. Those armed persons you note pay no attention to laws or they wouldn't have guns now.

Those are the people - intercity minorities, helped by others who evidently believe as you do- who barely voted down the concealed carry referendum in my home state. They don't want law abiding citizens arming themselves, they want to keep that all for themselves! Ordinary citizens carrying concealed firearms would present a serious threat to their activities and livelihoods!

>
> My own opinion is that gun laws won't decrease the murder rate much.

That has been the basic experience where guns have been banned. In fact Statistics reveal the violent crime rate has virtually always risen. .

> , the religious assumptions of some
> groups, that universal gun ownership will decrease crime and safeguard
> civil liberties are just that: dogma without any basis in fact.

Again, universal gun ownership is not an objective, it's the RIGHT to it that is at stake. No one wants to live in a nation where everyone needs to arm himself for protection, that's way off the screen for almost everyone. We DO live in a nation where many need to, now. Should they be prohibited by law from protecting themselves, their families and property? I think not. And I know that despite everything, a great many people do quietly arm themselves for protection, and intend to do so in the future, whatever the law, feeling that their survival is primary. I feel fortunate that I don't need to include myself in that group, but I certainly side with their philosophy. In our free country surely everyone has a right to provide for his own personal protection.

I agree, that's more than enough on the subject. But it's not a simple one, as some think..

Reg Edwards, G4FGQ wrote:
"Wot is a Thevenin?"

We could go to the books for the conditions of linearity etc required for validity, but in general, a Thevenin`s equivalent generator behaves as an open circuit voltage at its terminals which is delivered through a series internal impedance which is not limited to a resistor but may include a reactance. This internal impedance can be measured with all voltage sources shorted.

Magnitude of the impedance can usually be measured as the ratio of the open circuit voltage divided by the short circuit current.

Terman knows all and tells all in his 1955 opus starting on page 74. I probably haven`t read it in almost 50 years. I probably should have before responding, but I was lazy.

For those that don't seem to understand the concept...

Load = anything that is attached to your TX. Your antenna is (or should be) the PRIMARY load, but also a part of the total load are the coax (losses and VSWR), ground system, connectors, etc. All of these actually represent a fairly complex series/parallel load to the output of the TX.

For VHF, I would be concerned if it were this high at the middle of the band as it is apt to be higher at either or both ends of the band and that could start getting into an area of risk.

Under steady-state conditions with a lossless transmission line,
generated power = power to the load = forward power - reflected power.
90W = 90W = 100W - 10W

> Dee Flint, N8UZE

By the same token it is equally apt to go lower.
But that misses the whole point. Its not a question of reflected power re-entering the radio and causing problems. The output stage of your garden variety VHF solid state radio is working at a very low output impedance and by virtue of whatever output tuning circuitry it finds a 50 ohm load as the one to transform correctly back to the transistor...ie, the desireable current draw of the transistor is based on a 50-ohm load.
Stray from that and the collector current is going to be unhappy and bad things can happen...thats why they have the limiting circuitry and if thats working properly there shouldn't be any particular risk of damage. Its not the 'reflected power' thats the culprit...its the mismatch to the output circuit. Playing around with oddball speakers on a car stereo gives the same result for the same reason.

Hi Roy,

It is unfortunate that you have violated your own rule about the utility of a Thevenin argument in a matching argument. It does not work as a proof as much as you might like to portray it. It is seductively simple, but as Einstein once said, "keep it simple, but not too simple."

I will use the exact same scenario you have chosen and "prove" the opposite to show NEITHER argument is true as a proof of reflected power.

For those who have their hymnals ready, please turn to Terman, Norton's Theorem (footnote on page 75 of Terman's 4th edition) and sing along.

Thevenin and Norton circuits are interchangeable and wholly indifferentiable from the outside (you cannot tell which is which without going inside the black box). The Norton equivalent of a Thevenin source is simply the substitution of a constant current source for the Thevenin constant voltage source, and the translation of the internal resistance from a voltage series to a current parallel circuit.

So, we simply move the internal 50 Ohm resistor you have already specified across a constant current generator and attach the same transmission line and the same external 50 Ohm load. In this configuration we find EXACTLY the same voltage across the external load and by necessity, the same current through the load, and the same dissipation of heat as before.

By this arrangement, the constant current generator MUST supply a constant 2.828A to arrive at the same load conditions presented in the Thevenin model you offered. Nothing has changed at the terminals: the

load exhibits a dissipation of 100W with 70.71V across those same terminals.

We remove that load, just as you did, and all can confirm that the terminal voltage rises to EXACTLY the same potential found in the Thevenin model, 141.4V. The two models to this point are totally indifferentiable.

Now I violate Norton, just as you had violated Thevenin, by looking inside the box and observing the power being dissipated by the internal resistor and find in glaring contrast to your own finding that the internal resistor must now pass 2.828A through it (wholly in keeping with the property of a constant current generator) and that resistor which in the loaded configuration formerly dissipated the SAME 100W as the external resistor, now dissipates 400W - not your zero Watts. Thus, by your own logic, reflected power is real and has been proven by the same paradigm.

Thus, we are presented with conflicting evidence using the exact same components or their cross-equivalents (consult Terman to confirm).

Your proof is no more valid than mine, hence the failure of the argument's due entirely to those same aforementioned violations.

However, to examine this against the reality of life, SWR presents a hazard to equipment that your argument denies. An open, constant voltage source will not harm itself (barring poor engineering implementation) and this alone flies in the face of common experience with a transmitter driving an open circuit. In such a condition, the circuit has every chance of failing and due to heat (which your model does not offer in distinct contrast to reality) be it of conduction (Iï¿½R thermal run-away) or a high voltage arc (which either opens a connection, or leads to a short that again brings thermal run-away).

Further, the choice of a Thevenin model over a Norton model does not conform to design characteristics (the Norton model is almost a direct analog of today's solid state finals). Notably, a Norton model is inefficient in that it always dissipates power (once you've violated the black box to observe it) regardless of load. However, so does every common solid state transmitter in use by the majority of readers here.

I have often challenged folks here to monitor the current drain of their rig in the unexcited, but key-down condition to observe that baseline of lost power - it is considerable and easily accounts for 30 to 60% of the best condition that can be arranged with a full drive at key-down. In other words, most common solid state transmitters rarely exhibit 50, 60 or even 70% efficiency and this more closely aligns with the Norton model than it does with a Thevenin model.

This does not mean that our rigs are Norton sources, it also does not mean that our rigs are Thevenin sources. The simple fact of the matter is they are not linear and do not qualify in either regard.

But for practical purposes they do come close if we conspire to arrange our experiments. That has not happened here for either of us as both arguments are artificial, are in conflict (which violates equivalency, again consult Terman) and prove nothing.

I see that my main sin was to call the combination of a voltage source and series resistor a Thevenin source.

So let me retract that and call it a Lewallen source. Unlike Terman's Thevenin, I won't feel violated if you look inside my source. Perhaps that will allow you to see the point I was trying to make.

I do take issue with your "proof", however, and claiming to have "proved the opposite" of what I showed. I showed a single case in which the reverse power is not dissipated in the source resistance. It only takes the single example to prove that reverse power isn't dissipated in the source resistance. No number of examples showing a correlation between reverse power and dissipation will "prove the opposite" in the face of the single example to the contrary. I have shown a simple case where reverse power can't possibly be being dissipated in the source, even when it's perfectly matched to the line. Therefore, carefully constructed arguments nothwithstanding, I've shown that the reverse power isn't necessarily dissipated in the source resistance.

And, for that matter, I don't see that you've shown at all that the source of the power being dissipated by the resistor in your example is the reflected power. With the open circuited line attached and in steady state, you have 100 watts of reverse power on the line, and 200 watts being dissipated in the shunt source resistance. When you disconnect the line from the source, the resistor is still dissipating 200 watts, but there's no reverse power to furnish any of it. And the 100 watts of reverse power is still on the line. So we've changed the reverse power seen by the resistor from 100 watts to zero watts without any effect on its dissipation. How is it that this proves that reverse power is dissipated by the source or invalidates my example?

I have an old yagi antenna on the roof and I want to start using it.
It came with the house.

It looks very similar to this one:
http://www.channelmaster.com/layout_graphics/3014%20Antenna.jpg

I want to run a coax cable "the type used for catv" from the antenna
to my tv. The problem is I can't seem to find any places where a cable
would be connected. Do I just strip it and wrap it around any element?
Where does the middle wire go? and where would the braided wire that
sorrounds it go?

thanks

Why do you say 7 is too many?
Except for cable attenuation, more turns is better!

increasing the number of turns increases the interwinding capacitance. at
high frequencies this reduces the impedance of the choke. see some actual
data on http://www.k1ttt.net/technote/airbalun.html near the bottom of the
page. note that at 28mhz the 6 turn on 4.24" form has about 3 times the

impedance of the 12 turn one. also that 4 turns on 6.625" form has about double the impedance of 8 turns on the same form... and very importantly note that bunching the turns up instead of making a neat single layer reduces the impedance by a factor of 10! at 28mhz making it virtually useless at 10m while it is actually better below 7mhz.

hey stan
i dont have a vette but my mercery sable has a plastic trunk lid and
rear fenders so what i did is
i went to the website for hamstick antennas and they make a license
plate mount and basically what it is is a stainless steel plate the same
size as your license plate with a tab that sticks out either the top or
bottom which has a 3/8 24 thread mount on it and what you do is run a
ground wire from the mount to the frame somewhere close
it sells for i think $45 but it works well
i think there website is www.hamstick.com then click on products then
the mount button
good luck

Hi Roy,

In an earlier post you made the following statement:

>>
"The notion that reverse power is absorbed or dissipated by the load is a
myth, based on misunderstanding of the phenomena involved. It's very
easy to provide any number of examples to show it's simply not true."
>>

I think you need to be careful in how you make this statement and in what you imply by it. I think a more correct statement would be that the internal source power dissipation does not necessarily increase (or decrease) by an amount equal to the reflected power. In implying that reflected power is "not absorbed" or "not dissipated" by the source, many people presume that the only thing that can happen to the reflected power is that it must be re-reflected. If the source impedance is equal to the Zo of the transmission line, there will simply be no re-reflected power (voltage and current).

So, what happens to the reflected power? The problem in understanding the answer to this question is that we try to perform the transmission line/circuit analysis with power. The transmission line/circuit analysis must be performed with voltage and current.

The more technically correct statement in this problem is that the reflected voltage and current are delivered to the source. The internal source power dissipation is simply a function of the forward and rearward voltage and current developed across the source impedance.

Consider a simple example.

Let's assume that we have a 100 V source with a 50 ohm source impedance connected to a 50 ohm, 1 WL line terminated with a 50 ohm load. The steady state voltage across the source impedance is 50 V, the steady state voltage across the load is 50 V. The power dissipated in the source impedance and the load is 50 W. (I'm using |V|^2/R to determine P) The forward power in the line is 50 W and the reflected power is 0 W.

Now let's consider the situation where the line is terminated with an impedance such that the reflected power is 50 W. What is the total power dissipated in the souce impedance? The power dissipated in the source

impedance will range between 0 W and 200 W as direct function of the phase of the reflected voltage and current.

The total voltage delivered to the source impedance will be equal to V = Vforward - Vreflected. Vforward is the forward voltage delivered to the source impedance by the 100 V source voltage. Vforward will always be 50 V in this example. Vreflected is simply the reflected voltage.

Specific Examples:

V = Vforward - Vreflected

Short Circuit Termination: Vreflected = -50V; V = 50 - (-50) = 100 V. P = 200 W

Open Circuit Termination: Vreflected = +50V; V = 50 - (+50) = 0 V. P = 0 W

Load = 0 + j50 ohms: Vreflected = +j50; V = 50 - (+j50) = 50 - j 50. P = 100 W

We could come up with a number of examples to demonstrate these concepts.

If the source impedance is equal to Zo, there will be no re-reflected power. However, stating that the reflected "power" is delivered to the source is only valid in understanding that it is the reflected voltage and current that are delivered to the source.

The steady state power dissipated in the source is simply a direct function of the steady state forward and rearward voltages developed in the source.

In all cases, the levels of reflected voltage and current (therefore power) at the source are a direction of the source impedance reflection coefficient.

A similar analysis works if the source impedance is not equal to 50 ohms.

Hello
I have a FT 920 with the AM filter and FM board. The FT 920 is 100 watts HF + 6 Meters. It has a Auto tunner and the MC 100 Desk Mic. I also Have the 3 KW Roller Inductor Antenna Tuner. They are in good shape I will trade both for a FT 990 or a FT 1000.. I have been using the FT 920 as a backup rig.
If you have a FT 1000D I will add a Henry Radio 2KD-5 Amplifier to the deal. 100 watts in gets you about 1000 watts out. It has new caps and a pair of Emac 3-500. It is wired for Single Phase 240. The same voltage that runs your dryer and electric range. I am will to travel 100 miles from Athens GA. Drop me a email so we can work out the deal.
oris@dirtball.com
Happy Holidays

I hope I am in the right place and I really hope some one can help me.

I am quite a fan of FM radio stations but the problem is that poor reception is better then what I have where I live.

can someone recommend a good antenna or reciver or amplifier in a decent price .

thank you

Why do you present only voltage and ignore current? Voltage and current are
in phase in the forward wave and 180 degrees out of phase in the reflected wave.
Thus, no matter what the phase, as long as the energy in the forward wave and
the energy in the reflected wave remain constant, the current will rise when
the voltage falls and vice versa. The transmitter not only has over-voltage
protection. It also has over-current protection.

Hi Cecil,

The statement was made from the perspective that the analysis could be done knowing only the voltage and source impedance. The analysis could also be done knowing only the current and the source impedance. I figured it would be understood that if one knew V and Z, I and P could be determined. At the same time, if one knew I and Z, V and P could be determined. As long as you maintain the correct relationships between forward and rearward voltage or forward and rearward current, either reference would work fine.

It is also important to be clear on which direction (forward or rearward) one defines for a "+V" versus a "-V" and a "+I" versus a "-I". This is important in understanding whether to "add" or "subtract" the forward and rearward voltages and currents to determine the total voltage and current.

In making the following statement:

"Now let's consider the situation where the line is terminated with an impedance such that the reflected power is 50 W. What is the total power dissipated in the souce impedance? The power dissipated in the source impedance will range between 0 W and 200 W as direct function of the phase of the reflected voltage and current."

More to your point, I should have been more precise in the last sentence as follows:

The power dissipated in the source impedance will range between 0 W and 200 W as direct function of the relative phase between the forward and rearward voltages and/or the relative phase between the forward and rearward currents.

"And simultaneously bang goes the conjugate match!"

Yes, but only because the 5W forward and 1W reflected were givens. Were the match to the transmitter better or poorer, we likely would have had more or less than these powers. If the load on the coax is unchanged, 20% of the incident power at the load gets reflected.

Best regards, Richard Harrison, KB5WZI

The Radio Shack discone antenna is an easy to assemble omni-directional antenna. Put it together per the instructions and mount it as high as you can, preferably outdoors.

I believe they also sell FM antennas that are basically dipoles. Again mount it as high as you can. For example, near the ceiling is better than near the floor.

This "England " bit is somewhat of a distortion
Rapidly rising crime rate, what does that mean in actual comparable
statistics?
Is it because of 'guns'? Is it as bad as it is in the U.S.?
Are crimes mainly from non ethnic groups since all countries are now
wide open to those from other countries? (Gang warefare seems to
contribute to a lot of deaths in the U.S.)
Does England have the same rate of accidental killings or crimes of
passion
that prevail where guns are easily obtainable for "defense purposes?
How many policemen have been shot and killed by those that carry guns?
Many criminals will carry a baseball bat to accomplish acts of
violence rather than take the chance of increased sentences incurred
by carrying a gun.
The situation or discussion regarding the carrying of arms is fine but
clogging the discussion by bringing England into it is just not
relevent.

Source record: 129746

I've looked at the Fractal Antenna web site and can find nothing on there which gives any explanation of how this antenna works, or why it's supposedly superior to any other technology.

I looked up one of the patents they hold, but like many patents, it is devoid of any actual information about how the technology works. Unfortunately, this isn't anything new - for years, the US Patent Office has issued patents for things that simply don't work, or at least don't work very well.

I think there was a guy who invented the "Rubik's Cube", years before Professor Rubik did. His version of the cube used rubber bands which got twisted up inside and wore out very quickly. Nevertheless, he was able to sue the American manufacturers of the Rubik's Cube for millions of dollars, even though they didn't use any of his technology, just the idea (which Rubik came up with independently).

Moral: if you have an invention, patent it - even if it doesn't work. If some genius later on manages to find a way to make it work, you can sue him for "patent infringement". But I digress.

The only supposedly technical paper I can find describing this technology is now available as a reprint - for the paltry sum of $25 US. The fact that Dr. Cohen seems to think that a technical paper he wrote 7 years ago for Communications Quarterly is worthy of such collector status makes me question his understanding of the scientific method. I can buy the entire set of Communications Quarterly magazine from 1990 to 1999 on CD-ROM for $39.95, for crying out loud (http://www.radio-ware.com/books/ar-cdcq.htm) assuming it's the same Communications Quarterly. If it is, then it does not appear to me to be a refereed journal.

I read the first page of the reprinted article (that's available for free) but it contains nothing of substance, except what I consider a mistake near the bottom of the page, where Dr. Cohen states "Constructions of 'classic' (Euclidean) geometry have dominated [continued on next page, which I don't have]". If he's saying that constructions of Euclidean geometry have dominated antenna design, this is no more relevant than saying they've dominated table manufacturing; most tables are circular, square, rectangular, or occasionally triangular. But I don't think the principles of Euclidean geometry have much to do with antenna design, beyond pointing out that every physical object must have a shape, and some shapes are better suited to antenna construction than others.

In accordance with a first aspect of the present invention, there is provided a transportation facilitation device including a circular rim, a bearing in which a hollow cylindrical member is rotatable about a rod situated within the hollow cylindrical member, and a series of connecting members connecting the circular rim with the hollow cylindrical member to maintain the circular rim and the hollow cylindrical member in substantially fixed relation, wherein the rod is positioned on an axis perpendicular to the plane of the circular rim, and substantially central of the circular rim.

Abstract from John Keogh's successful 2001 application for an Australian patent (Innovation Patent #2001100012) for the "Circular transportation facilitation device" aka "wheel".

So we have a key down ham transmitter that sees a virtual open circuit. Are you saying it won't dissipate any power while it maintains the standing waves? Ever try that with an unprotected transmitter? I forgot to hook the antenna up to my ARC-5 one time and burned up the 1625's. You are mistakenly allowing your model to try to dictate reality instead of the other way around. There is no possible way to maintain standing waves on a transmission line without dissipating power in the source. Most ham transmitters will fold back when looking into an open circuit for the purpose of keeping them from burning themselves up. Your model does NOT correspond to reality.

If you can set such an experiment up on the bench, you can demonstrate standing waves without a power source. Have you patented your magic energy machine yet? I've got a picture of it on my web page at: http://www.qsl.net/w5dxp/magic.gif

Hi Roy,

You can say that again.

>
>So let me retract that and call it a Lewallen source. Unlike Terman's
>Thevenin, I won't feel violated if you look inside my source. Perhaps
>that will allow you to see the point I was trying to make.

This simply casts the issue back into what constitutes a Lewallen
voltage source (as distinct from the over-all Lewallen source). You
are simply crafting the scope after the fact to fit the argument.
Problem is the remainder of your apologia then goes to assume your
retraction and you argue that as a defense against my comments. Is
this Zen archery?

>
>I do take issue with your "proof", however, and claiming to have "proved
>the opposite" of what I showed.

Roy, that is NOT what I said:
>> I will use the exact same scenario you have chosen and "prove" the
>> opposite to show NEITHER argument is true as a proof of reflected
>> power.
And I did not isolate that to one simple escape clause, but reinforced
it continually:
>> Now I violate Norton, just as you had violated Thevenin,
or
>> Your proof is no more valid than mine, hence the failure of the
>> argument's due entirely to those same aforementioned violations.

You may have an issue, but you do not address it except in terms that
I have clearly qualified, admitted to, and dismissed. Restating my
own admission, without attribution does not qualify as an argument
against me and it certainly does not qualify as new testimony from
you.

> I showed a single case in which the
>reverse power is not dissipated in the source resistance. It only takes
>the single example to prove that reverse power isn't dissipated in the
>source resistance.

And this is different from my counter proof that clearly employs the same logic? You have been shown a single case that denies your logic. The logic does not hold and THAT has been demonstrated.

>
>And, for that matter, I don't see that you've shown at all that the
>source of the power being dissipated by the resistor in your example is
>the reflected power.

Again, nothing in my post suggests I was offering a proof of reflected power as I have admitted IT DOES NOT many times. Ascribing such motives to me to leverage an argument does not compel.

You were entirely right to confess to your sin, but expecting contrition from me for it is as poor logic as where you started. Learn to separate the criticism of the logic/proof from an attack on the topic being offered.

Exactly. Forward waves and reflected waves are transparent to each other until they encounter a real impedance discontinuity at which point their reflections can cause wave interference between their components.

4116. help with 70 cm beam

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-07 20:49:38 UTC
From: Whovian <smitty@gallifrey.zzn.com>
Message-ID: <Xns92DDA15A14CB9smittygallifreyzznco@216.168.3.44>
Source record: 129755

Hi all, I would like to build a 70 cm multi element beam but I don't know how long to make the driver and elements or how far apart they should be spaced. I was hoping that someone here could help me out.

thanx

4117. COAX types and performance

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-07 21:02:24 UTC
From: adam.white@sbcglobal.net
Message-ID: <3df2542a.264773964@news.dallas.sbcglobal.net>
Source record: 129756

Being new to the HAM game, living quite some distance from the nearest supplier of HAM components, and being tight on cash all encourage me to do as much homework as possible before buying items to build my HAM setup. Most recently I've been looking at COAX cable and I dug up the following statistics (listed in order): dB attenuation per 100 ft. at 10 Mhz, dB attenuation per 100 ft. at 50 Mhz, Impedence, Max operational Voltage, and price per foot at a local supplier.

Belden RG-8/U (#9913): 0.40, 0.9, 300, n/a
Belden RG-8/x (#9258): 0.90, 2.1, 300, $0.19 ***
Belden RG-58/U Type (#9201): 1.10, 2.5, 1400, $0.22.
Belden RG-213/U QPL (#8267): 0.55, 1.3, 3700, $0.55
Times Microwave LRM-240 ultraflex: n/a, 1.9, n/a, $0.47
*** Note: I'm assuming this is what is commonly called 8x-mini ???

I'm wondering how significant to me and my little application the various specifications will be -- I plan to use a little (less than 100 feet) COAX as feedline for a 20m dipole. I understand the importance of attenuation, but it appears to me that the attenuation for ANY of these cables on such a short run would not be a problem. But I'd like your thoughts on this. The price difference between any of these options is not really significant (difference between $20 and $40) ... but now that I've started looking at these stats, my curiosity is aroused.

And what about that "max operational voltage" number? Is that significant for a standard HF transceiver running no more than 1500 watts?

There's also the question of shielding. I did not include the spec's on shielding. Would the shielding on any of these cables be problematic for me?

A final question: I noticed that some COAX has a single conductor and some of it has multiple strands. For example, the RG-8x listed above has 19 strands, while the others have only one. Aside from the price difference (stranded cables appear to me to cost about half of the amount for the same sized single-strand conductor), is there any meaningful difference between stranded conductors and single-strands?

Thanks in advance.
Adam

Certainly, what's your point?
I can demonstrate self resonance with ANY coil.
What was proposed was that adding LINEAR turns to a balun increased the
capacitance.
"increasing the number of turns increases the interwinding capacitance."
This is FALSE!

I never said or meant to imply that a transmitter would dissipate 0 power
when connected to an open circuit.

As long as there is a closed path for current through a dissipative
impedance somewhere within the transmitter, power will be dissipated.

I'm aware of that.

>Your model
> does NOT correspond to reality.
>

I never said that the model I described represented a transmitter. It is
and was only intended to be a simple model for the purpose of describing
simple concepts. These concepts can be validly applied to the transmitter
if a correct and complete circuit model of the transmitter is constrcuted.

That's actually quite funny, however, it is not a figure from my QEX article nor does it represent the concepts associated with superposition as described in my QEX article. Fortunately, most other people on the NG probably understand the concepts of voltage and current superposition in circuit analysis.

Take care,

Greetings,

Surely this is an old topic. However, still interesting.

Take a vertical dipole, Force 12 Sigma 5 for example, is there benifit to mounting high - say on tower at 110 feet - versus low nnear ground.

Some say there is no benifit to mounting a vertical high, others say high is better - period.

Your thoughts?

Thanks.

Make the dipole 1/2 wavelength long and use a number of 1/2 wavelength
lengths of 450 ohm ladder-line with which to feed it at 14 cents per foot.

So such concepts exist only in your mind and not in reality? If your concepts don't apply to amateur radio transmitters, why are you presenting them on an amateur radio newsgroup?

> That's actually quite funny, however, it is not a figure from my QEX article
> nor does it represent the concepts associated with superposition as
> described in my QEX article.

It's not a figure from your article, Steve. It only references a figure from your article. And of course it represents your concepts, Steve. You posted the equation 75W + 8.33W = 133.33W right here on this newsgroup about a year and a half ago before you published your article. You said in your article that you can take 61.24V@1.225A (75W) and combine it with 20.41V@0.408A (8.33W) to achieve 81.65V@1.63A (133.33W). That drawing is exactly what you have said diagrammed into a picture that is worth a thousand words.

Here's a quote directly from your QEX article: "In this case, the forward source power of 92.831 W combines in-phase with the re-reflected power of 0.555 W, resulting in a total forward traveling power of 107.736 W." Can you tell me any other scalar value in existence besides your magic power that can be added to obtain *greater* than the sum of the ingredients? Have you ever seen 92.831 gallons/sec combine with 0.555 gallons/sec to achieve 107.736 gallons/sec?

Criminals always want to rob liquor stores. They don't do it very often
in Texas because they are likely to die. There is nothing to stop them
from doing so in England since they know the liquor store owner is probably
not armed and if the owner were to shoot them, the owner would be the one
going to jail. If you were a robber, would you rather rob an armed person
or an unarmed person?

Source record: 129767

Adam,
As far as loss goes, any of the coax types you have listed should work okay. The RG-58 has the most loss so would be my third choice.
The kind of wire used for the center conductor (solid or stranded) has more bearing on how flexible the cable is rather than how well solid or stranded wires conduct. The stranded cable tends to be more flexible and a bit easier to work with.
The better the coax is shielded, the better off you are. If it's a matter of a couple of percentage points difference, I doubt if it makes a lot of difference on HF.
The maximum operating voltage tells you how much power you can run at a particular SWR. [V = SQR(SWR x Watts x Impedance)] Plug in some example numbers to that equation and see what the voltage is on your feed line. The closer the 'V' to the maximum voltage rating of the coax, the more likely you are to cause damage to the feed line (it's also smart to include a 'fudge-factor' in that max-voltage rating to give your self some safety margin).
'Doc

4131. Was Terman infallable?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-08 00:56:07 UTC
From: aunwin@insightbb.com
Message-ID: <85ed38d.0212071656.41ac05a3@posting.google.com>
Source record: 129670

Since Terman and his writings are refered to often on
this forum I grabbed a hold of Radio Engineering by Terman
to see what he had to say about properties of resonant.
circuits. What interested me was the portion titled
'Coupled circuits with Untuned Primary and Tuned Secondary.
By golly his discusssion describes exactly my antenna which
the Gurus on this forum reject! How can this be? As I look back I see
that mathematics has undergone change with the introduction of New
Math.

Is it possible that resonant circuits have undergone a similar
change at the hands of the modern Guru. He also draws the circuit
of such a coupling which exactly represents a coupled antenna
tho he gyrates more around the audio portion where the degree of
coupling between the circuits is fixed. I then looked to see what he
had to say
regarding a similar arrangement that resembled my next antenna but
with the
added use of varying coupling.
By golly he also talks of such an arrangement at length including
the critical coupling factor! Why is it that todays Gurus do not
accept what Terman states and have now come around to the point
that Termans findings now require proof.
Just to remind all of the UNWIN antenna it consists of a
random radiator like a dipole tho it may be fed differently to
the normal dipole which is normally at it's center.
This radiator can be drawn as a untuned circuit and matches that
drawing that Terman relates to. The second portion of my antenna
consists of a TUNED circuit just as Terman describes, which
also reflects a variable frequency loop antenna. This again is
exactly as shown in the fig shown by Terman.
He then goes on to discuss exactly what happens when both circuits
are tightly coupled which is the antenna I previously described.
He then goes on to describe the characteristics of such an arrangement
where the degree of coupling is changed which is exactly the path that
I am now taking by placing part of the Tuned Secondary circuit
away from the influence from variable coupling.
Would the Gurus on this forum please explain why Terman was
incorrect with respect to coupling of circuits even tho he
appeared accurate regarding the change in Q with respect to my
antenna compared to that of a loop antenna alone .
No one can be really infallable, but the modern Gurus are
suggesting exactly that in the past statements upon my antenna
which reflect Termans teachings has been subject to new

interpretation.
This posting is made because of the offer made by Roy a month
ago where he invited me to explain my antenna once again.
Roy is known to be a Guru and often referes to writings of
Terman as other Gurus do on this forum, so he as other Gurus are
well versed in "older" teachings on resonant circuits and
presumable the "new " changes in interpretation.
Best regards to all
Art Unwin KB9MZ....XG

At one time, in San Francisco, there were many, many, mom and pop grocery
stores. There were probably very few of them where the owner didn't keep a
gun behind the counter. They were held up on a regular basis and, yes, there
were robbers who were killed, but there were also store owners who met the
same fate. The point is, that stickup men are such a stupid breed
that the prospect of getting killed doesn't always enter into their
calculations.
My wife's father was killed in a holdup, but the fellows who killed him
didn't have much of a chance to enjoy the money they stole because
they were gunned down by cops a couple of days later trying to
rob another merchant. If I were a robber would I rather rob an armed person
or an unarmed person? I'd take up another profession before I'd do either.

Adam,

At 1500 W the peak voltage at 50 ohms is about 275 Volts. You should really look at the power spec, not voltage; high voltage RG58 will not take the power that corresponds to your Table. BTW, there is a version of LMR240 that is not Ultraflex. It is cheaper and lower loss than the flexible. The only thing I would not do with it is run run it around an antenna rotator. I have put a KW into it at 10-80 meters with no problems in a reasonable SWR circuit. I have also used 8X on 80 meters with a KW. The 240 is much better than the 8X for loss and shielding. Don't buy the old style 9913, if water gets in one end, it comes out the other. Note that there are several types of 9913. These are only a very small subset of RG8. RG213 is WW2 technology military RG8. Lastly, with a dipole, consider the weight.

As i recall, the FM band lies between Ch6 and CH7...so a Radio Shack TV antenna would also work. If you hv cable TV, have you tried connecting the cable to the radio?

In case you are more confused, it is probably a 300 ohm balanced antenna, not meant for use with cable. There should be a couple of wing nuts or the like for connecting the 300 ohm twinlead to. To use cable, you need a 300 ohm to 75 ohm transformer, aka balun. Get the kind that has an F connector on one end, and pigtail wires on the other end. In case the nuts are missing, look for two bolts sticking out that the nuts may have been screwed on to. They will typically be an inch or two apart. Are there pieces of wire sticking out anywhere - if so, that's it.

Nat,

Remember that V and I are complex numbers. So, if you have 1 V, and 1ma with a phase shift of 45 degrees, the impedance is 1K at -45 degrees, or 707 - j707. If you just want to measure loss, there are easier ways.

4138. 80 meter "Skywire Loop" antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-08 02:05:12 UTC
From: rckchp@comcast.net
Message-ID: <6dc33f40.0212071805.281d729d@posting.google.com>
Source record: 129676

I am going to try an 80 meter "Loop Skywire" antenna, as described in an article by Dave Fisher, W0MHS (he has a different call now)in the Nov 1985 issue of QST (also in some editions of ARRL Antenna Book and is available to members on the ARRL web site via search).

I'm going to try and keep it somewhat "stealthy", so I plan to use some #22 insulated wire. What I've got is a 1000' spool of twisted pair(insulated single strand tinned copper). An 80 meter loop will be approx 257.5' and it will be a bother to untwist that length, it has 1 twist every 2". Will there be any problems or "quirky" behavior if I leave it twisted.....just bare, twist and solder the ends? Also, the wires are white and orange....I'd like to soak the whole spool in black dye to make is less visable....any problems doing that? Has anyone done this? Thanks,

Rich K2CPE

Rich,
I don't think you would have any problems using the 'pair' like you said. With one of the wires being orange, you might want to 'un-twist' it to get rid of that color. I don't think you're going to have much luck dying it, or painting it. White should work out fairly 'stealthy'.

On Fri, 06 Dec 2002 16:51:33 -0800, Roy Lewallen <w7el@eznec.com>
wrote:

|Ok, here's a case for consideration.

Now you're changing the parameters.

You asked, "If only sometimes, what are the necessary conditions?"

I replied,

"A = B

Where:

A is a generator with a good source match (Zg). For example Richard
Fry's solid-state amplifier with 20 dB return loss. In transmitters
this is often accomplished by using quadrature couplers with the
fourth port port terminated in a matched load, or at microwave,
isolators (terminated circulators). Reflected power is "dumped" into
this load. (But you know that <g>)

B is a transmission line with Zo equal to Zg."

I wasn't considering any other cases, only the above.

I've spent the last two days getting ready for and attending a ham
swapfest and while I was away I see a lot of other answers to what
follows. I'm just going to standby and watch <g>

|
|A = a generator consisting of a Thevenin source: a voltage source with a
|50 ohm series resistor. This is a good model of a laboratory signal
|generator of the type used for HF measurements. I'll make the open
|circuit voltage 141.4 volts RMS, which is the voltage of the voltage source.
|
|B = a lossless 50 ohm half wavelength transmission line.
|
|This is, wouldn't you agree, a situation where there's a perfect match
|at the input to the cable?
|
|First let's terminate the line with a 50 ohm load. The load will
|dissipate 100 watts. The reverse power on the line is zero. The
|dissipation in the source resistor is 100 watts. So here we have a
|situation where there's no reverse power, and the source resistor is
|dissipating 100 watts. The voltage source is producing the 200 watts
|being dissipated by the two resistors.
|

|Now open circuit the line. We find that the forward power is still 100
|watts. The reverse power is 100 watts. There is no load to dissipate
|power. The source is delivering no power. The source sees an open
|circuit. The dissipation in the source resistor is zero.
|
|Now, here's a case where clearly there's a perfect match between the
|source and the transmission line. There's 100 watts of reverse power on
|the line. Yet the source resistor is dissipating nothing. At least for
|the simplest case I can think of, a Thevenin source driving a matched
|line, the reverse power clearly isn't being absorbed or dissipated by
|the source resistor. In fact, when the reverse power went from zero to
|100 watts, the source resistor dissipation went from 100 watts to zero.
|
|If you put an isolator between the source and the line, it's a somewhat
|different story. Then, the source sees 50 ohms even when the line is
|opened at the far end. Consequently, the voltage source continues to
|produce 200 watts of power. 100 watts is dissipated in the source
|resistor and 100 in the isolator termination. I suppose it would be fun
|for some folks to argue whether the 100 watts dissipated by the source
|resistor is reverse power, whether the 100 watts dissipated by the
|isolator termination is the reverse power, or whether both are simply
|the the power being produced by the source. In fact, when you disconnect
|the line altogether, there's no longer any reverse power. And the
|dissipation in the source resistor stays at 100 watts and the isolator
|resistor at 100 watts. This makes it difficult to justify the need for
|reverse power to produce dissipation in the isolator termination. A
|simple explanation based entirely on load resistance will suffice, and
|it'll accurately predict the isolator termination dissipation regardless
|of line impedance or the amount of reverse power on the line. For
|example, if we connect the isolator to a 450 ohm half wavelength line
|terminated in 50 ohms, we'll have 278 watts forward and 178 reverse on
|the line, yet the isolator termination resistor will have zero
|dissipation. This is easily explained if you entirely ignore the reverse
|power and simply look at how the termination dissipation varies with
|load impedance. That holds true for *any* kind of steady state source,
|including an isolator or Thevenin source.
|
|The notion that reverse power is absorbed or dissipated by the load is a
|myth, based on misunderstanding of the phenomena involved. It's very
|easy to provide any number of examples to show it's simply not true.
|

4144. Self-resonant RF Chokes

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-08 03:09:54 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <asud61$2lc$1@knossos.btinternet.com>
Source record: 129681

On this newsgroup the usual haggling contest is presently in progress. The subject matter is the natural resonant frequency of neatly-wound, single-layer, solenoids such as tank coils, loading coils, helical antennas, and of course RF chokes including the coaxial variety.

Program SOLNOID2, amongst other things, for given coil diameter, coil length, number of turns, ratio of wire diameter to winding pitch, calculates the resonant frequency in question. Principal input data can be varied up/down from the keyboard to adjust resonant frequency to any required value.

For anyone interested the calculating formulae used in the program is equivalent to -

Cself = Length / P / 74.25 picofarads where -

Length = Coil winding length in millimetres.

P = Ln(J + Sqrt(Sqr(J) + 1)) + 1 / J - Sqrt(Sqr(1 / J + 1) where -

J = Length / Dia / 2

Dia = Diameter in millimetres of coil between wire centres.

Resonant frequency = 159.2 / Sqrt(L * Cself) Megahertz.,

Where Cself is the equivalent shunt capacitance across the coil, and -

L = Coil inductance in microhenrys available from a variety of sources including program SOLNOID2 itself.

I hope I have not made a typing error in translating the above formula for Cself directly from program source code. It cannot be obtained from elsewhere. Copy it into your technical notebooks.

Self-resonant frequency can be accurately measured directly with an antenna analyser like Autek. Place a thin-wire, single-turn link-coupling around the center of the coil under test. Connect the link to the antenna analyser, on the Z range, via 9 to 12 inches of loosely-twisted pair. Vary frequency until a very sharp Z peak is observed on the analyser. If you are not careful you can miss it.

Yes, stray coil capacitance, contrary to Old Wives' baffle-gab and the manuals, yields a high Q. See it for yourselves !

Accuracy? Good enough for the intended purpose. As soon as any wires are connected to the coil under test its resonant frequency will decrease slightly. But probably not enough to worry about.

In the case of coaxial chokes the stray capacitance will be slightly increased by permittivity of the insulating jacket and Q will decrease relative to bare wire. Wire diameter and winding pitch are that of the coax braid.

Program SOLNOID2 has a number of other applications. For example its self-capacitance formulae is incorporated in program MIDLOAD, a very short centre-loaded dipole with additional end-loading wires.

Lots of plans on the 'Net. To start, try the quagi on 432/440. Here's a
reference to get you started:

http://www.geocities.com/garyntricia/quagi.html

Do a google.com search for quagi and 440 or 432. You'll get lots of hits. I'm
running a 12 ele quagi....took 3 hrs to build and I've had QSO's over 100 mi on
SSB (and alot farther via satellite!) using this antenna design.

> power of 92.831 W combines in-phase with the re-reflected power of 0.555
W,
> resulting in a total forward traveling power of 107.736 W."

And the two sentences immediately following this statement, that you
conveniently forgot to mention above, are the following:

"Again, it is significant to notice [note] that this "addition" of power is
determined entirely from the vector addition of forward voltage and current.
It must be understood that it is really the two forward voltages and
currents that combine, rather than the two forward powers."

>Can you tell me
> any other scalar value in existence besides your magic power that can be
added
> to obtain *greater* than the sum of the ingredients? Have you ever seen
92.831
> gallons/sec combine with 0.555 gallons/sec to achieve 107.736 gallons/sec?
> --

The discussion in the QEX article was in reference to the superposition of
two forward waves in a transmission line. The transmission line Zo in the
QEX example was 86.603 ohms.

Wave 1, when considered independently in the line, has an associated forward
voltage and power of 89.658 V and 92.821 W, respectively.

Wave 2, when considered independently in the line, has an associated forward
voltage and power of 6.935 V and 0.555 W, respectively.

When Wave 1 and Wave 2 are superimposed in the line at the same time, the total forward voltage is determined from the vector sum of 89.658 V + 6.935 V and therefore becomes 96.593 V (the voltages are in-phase). The total forward power is therefore equal to 107.736 W.

The point of my power addition statements was to demonstrate that when two forward waves superimpose in a transmission line, the total forward power cannot be determined from the algebraic sum of the individual powers (except when the waves are 90 degs out of phase) . Forwards powers do not superimpose algebraically. Forward voltages and currents superimpose algebraically (actually, they add as complex vectors).

My previous newsgroup statement that 75W + 8.33W = 133.33W, was made in reference to the in-phase superposition of two forward waves, one having an associated independent forward power of 75 W, the other having an associated independent forward power of 8.33 W. When these two waves superimpose, the total forward power becomes 133.33 W. Nothing more was implied by these statements.

I think its time for us to end this discussion on the superposition of power. I will not respond on this subject anymore on this newsgroup.

Bafflegab! Each wave contains a fixed amount of energy. If the voltage and current are in phase, that energy is V*I joules/sec. If the energies don't add up, then you are mentally violating the conservation of energy principle.

> The discussion in the QEX article was in reference to the superposition of
> two forward waves in a transmission line. The transmission line Zo in the
> QEX example was 86.603 ohms.
>
> Wave 1, when considered independently in the line, has an associated forward
> voltage and power of 89.658 V and 92.821 W, respectively.
>
> Wave 2, when considered independently in the line, has an associated forward
> voltage and power of 6.935 V and 0.555 W, respectively.
>
> When Wave 1 and Wave 2 are superimposed in the line at the same time, the
> total forward voltage is determined from the vector sum of 89.658 V + 6.935
> V and therefore becomes 96.593 V (the voltages are in-phase). The total
> forward power is therefore equal to 107.736 W.

You conveniently left out the energy involved in the interference pattern which is exactly the energy needed to balance the energy equation. Since the interference voltages and currents go to zero, they don't affect the voltage and current equations but they sure do affect the energy equation. Did you really think nobody would notice your slight of hand in attempting to disguise the re-reflected power as something else?

> The point of my power addition statements was to demonstrate that when two
> forward waves superimpose in a transmission line, the total forward power
> cannot be determined from the algebraic sum of the individual powers (except
> when the waves are 90 degs out of phase) . Forwards powers do not
> superimpose algebraically. Forward voltages and currents superimpose
> algebraically (actually, they add as complex vectors).

Powers add as simple scalar values. 92.821 gallons/sec plus 0.55 gallons/sec equals 93.376 gallons/sec, not 107.736 gallons/sec.

> My previous newsgroup statement that 75W + 8.33W = 133.33W, was made in
> reference to the in-phase superposition of two forward waves, one having an
> associated independent forward power of 75 W, the other having an associated
> independent forward power of 8.33 W. When these two waves superimpose, the

> total forward power becomes 133.33 W. Nothing more was implied by these
> statements.

You conveniently ignore the 50 watts of re-reflected power from the constructive interference pattern thus mentally violating the conservation of energy principle. The correct energy equation is 75W + 8.33W + 25W + 25W = 133.33W, where the two 25W values are two reflected powers involved in destructive interference. That makes the 50W of constructive interference re-reflected power. Everything except the 75W is re-reflected power. That fact makes about a dozen of your article statements false.

> I think its time for us to end this discussion on the superposition of
> power. I will not respond on this subject anymore on this newsgroup.

There's no valid way to add two scalar values to get more out of it than you put into it. You seem to have invented supersuperposing of powers.

4148. Re: COAX types and performance

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-08 04:57:48 UTC
From: Tarmo Tammaru <t-tammaru@home.com>
Message-ID: <BeGdnQ91s6tVTW-gXTWc3Q@comcast.com>
Source record: 129686

Here are some numbers for you, at 30 MHz, which is worst case for HF.

CABLE LOSS/100' POWER

RG58 2.5 DB 400W
RG8X 2.0 350
RG213 1.2 1800
9913 0.8 2200
LMR240 1.3 1490 (NOT Ultraflex)

The RG8X power rating is probably not meaningful, because every
manufacturere has their own version of that.

Hello,

I am working on an extremely low power (<<1W input) AM transmitter and have encountered several difficulties including how to determine the required impedance of the modulation transformer.

Any comments or suggestions on this or anything else (operating point etc) would be appreciated.

Thanks.

Joel

Cecil,
You are staing statistics that without explananation are meaningless
If there is a report that crime soared 100% with respect to guns one
must ask what number of crimes was the 100% refered to as just 100
crimes per year with the use of guns and then try to equate it for for
personal debating reasons
to say a state where it is normal to have ten times as many crimes per
capita with the use of guns and the increase this year was only 5%.You
just can't use
the statistics olone to justify any point that you want to make just
by playing with a statistic which alone is not related. It is just
like saying guns don't kill people it is people that kill people and
use that statement as a reasoning point for all to own guns. I
recognize that Americans have a history with respect to guns but this
same history is not carried by all countries. As a foreign born person
I could not argue one way or another but I can point to a place where
a statistic from one Country is completely irrelavent when compared to
the U.S. especialy when only percentages are used instead of actual
numbers.
I have not made this posting as an advocate for or against the
posession of guns, only the manipulation of information purely to
justify a particular argument. For me the mention of England made my
intrusion more necessary.
I would rather you state how many policemen in both countries per
capita where I believe it would show that more gun ownership in
England would bring the killings up to par with that in the U.S. but
then saying it that way would not bolster your position which you
tried to do by using statistics alone with out numbers. Enough said.
Regards
Art ....XG

Source record: 129694

well,
I do find this commentary more than enlightening. I did a google search for relivant items myself and came up with only 1 item on anything published 9and the link you provided matched what I found). the rest of the stuff that popped up were, for the most part, archived snippets from this (and other) newsgroup(s).

I don't call being publisjed 1 time in :Communications Quarterly" to be sufficient credentials. I would believe thos credentials if they showed up in the IEEE journal, IEEE Spectrum magazine, Spread Spectrun Scene, ETRI Journal, and dozens of others I could name.

I'm sorry to say this about nathan cohen and chip (whatever his last name is) but when the chips are down (sic), they just don't measure up to the task. they talk a good line, but the SWR is just too high for them to radiate very far into the credible world.

If they were really interested in good solid research, they would have gotten a grant from the NSF or some private organizations, done the research and published verifiable results. thats the scientific method (remember? observe, test and revarify with independant testing from multiple sources).

Now, mind you, I'm no scientist. I am a security specialist in computer security concepts (firewalls, encryption, etc), so this area is not my specialty. However, I know a line of bullshit when I hear it. Fractenna needs to lay it down on the line, post some simple kit ideas (full description) and have some field tests done to verify the results. if they can't do this, then they are spounting pure, unadulterated bull.

no results = no credibility.

Hello,

A balun is necessary for any Symetric antenna fed by coaxial cable.

And if you had 5/8 cable, would you want to wind it?
No surely not! Don't waste your cable lengths.

Just put ferrite tubes over your RG8, 6 or 8 in. long should be right. Here in France I found the right ferrite tubes by Radio Spares Components they are 5 cm long and fit just over RG-213 or RG-8 cable.

An antenna made with a twisted pair will allow a remote relay (inserted in the antenna wire) to be operated from a DC supply and an RF choke in the shack.

By isolating the wire beyond the relay a single relay contact can change resonant frequency from one band to another. Positive in action. No fiddling about pruning antenna traps. Use a reed relay which has very low capacitance between contacts. Use vaccuum filled type for high power.

Been there. Done that.

Doc, you slightly exaggerate what the manufacturers say. Of course, safe load depends on whether the cable is to be used in Guatemala in mid-summer at noon, or Alaska in mid-winter at midnight.

For more informative data on solid polyethylene coax power ratings versus frequency, swr etc., indoors/outdoors, wind, ambient temperature, download program COAXRATE from website below.

Lets say I have a 100 foot piece of 50 ohm coax, to be used at 30 Mhz. Lets also say that this piece of coax has a measured loss of 2 Db at 30 Mhz.

Now I take this piece of coax and cut it into 2 pieces. I then install 2 each PL259's, and splice the cable back together with a barrel connector.

The loss of this 100 foot cable with the splice would now measure approx what at 30 Mhz?

I don't believe I've seen these before. Are they manufactured in the
UK or do you homebrew them?

If we were to build our own, how would we fill the relay with
"vaccuum", just pour it in or what?

Will there be a downloadable in a few seconds -- not zipped-up -- run
immediately -- user friendly program to design these?

> by carrying a gun.

Art, I spent 30 years working with the police and I can't recall a single case where the perp
was armed with a baseball bat. I do remember one where the robber was armed with a large snapping turtle with which he threatened a store clerk. Should we outlaw turtles?

Begging your pardon, it is indeed relevant merely by example of a path to NOT be followed, as
is Australia. Too bad those folks didn't have forbears with the forsight to demand a Bill of
Rights.

For a yagi trap, which uses distributed capacitance and is made from
unknown materials, just how would you be calculating the loss or the
power handling capability?

Usually it does unless they're whacked out on some substance, then all bets are off. But then I'd be even more determined to defend myself since the drug crazed seem to often be more likely to shoot the victim for no reason.
Those people when not drugged are actually mostly cowards. They don't relish the idea of being shot by a victim. But if they know the victim is not likely to be armed because the law forbids him from it that gives them all the assurance and encouragement needed. The idea that he might have to face some store owner's blunderbuss IS daunting, even to the stupid.

>
> If I were a robber would I rather rob an armed person

Of course. But that doesn't change the fact that robbers prefer unarmed victims for a very good reason. It stacks the deck very much in their favor.

The antenna is probably more important than the receiving equipment. Check you
local Radio Shack. They have simple indoor FM antennnas, as well as a couple of
outdoor FM beam antennas that would go on your roof.

According to the QST review, the manufacturer recommends not mounting the Sigma 5 too high above ground. They also recommend bringing the feedline out, horizontally, from the antenna, which might be tricky on a tower mounting, maybe not.

single impedance.

>
> There's no valid way to add two scalar values to get more out of it than
you
> put into it. You seem to have invented supersuperposing of powers.
> --

In the superposition of multiple vector voltages and currents, it is the
multiple individual vector voltages and currents that add, not the multiple
individual scalar powers.

Power is a scalar quantity determined from the |V|^2/R, the |I|^2 R or the
product of |V| |I|, assuming that the impedance is a pure resistance R.

Lets work with voltages.

When two vector voltages (V1 and V2) add, the magnitude of the total voltage
(a scalar value) will never exceed the sum of the magnitudes of the
individual voltages (a scalar quantity). I.e., the vector voltage Vtotal =
V1 + V2 and |Vtotal| can never be greater than |V1| + |V2|.

The same is not true for the square of the magnitude of the voltages, which
is the scalar power. I.e. The vector voltage Vtotal = V1 + V2 and
|Vtotal|^2 can be greater than |V1|^2 + |V2|^2. Its also true that
|Vtotal|^2 can be equal to or less than |V1|^2 + |V2|^2.

For this reason, superposition of individual scalar powers cannot be used to
determine the total scalar power resulting from the vector addition of two
vector voltages and currents.

In vector superposition, Ptotal is not equal to P1 + P2, unless the
associated vector voltages, V1 and V2 are 90 degrees out of phase.

I am running a mosely tr-33 beam on a 45ft tower I get alot of rf feedback in my audio on 10-15 and some parts of 20 meters, is there a coax choke that I can make to cure it for the 3 bands? I have other antennas for 17& a 10 verticle and they do not bother but they are not on the same tower, I have run at least 5 different radios and they all do it, one other thing is that my tower runs up the wall outside right behind the radio so when I'm using the mosely the radio is directly under the antenna(45ft) should that be ok? I could possibly move the tower behind the garage but it would still only be about 30ft away and most of you know its no simple job to move a tower, I have read about people making coax chokes but they all seem to have different turns and diameters, is there one size coax choke that that I can make to cure all 3 bands? any help would be great Dale Kb1eod

> Art,
> I really don't think anyone was refuting Terman. I
> think it has more to do with how you relate ~your~
> antenna to what Terman describes.
> 'Doc

Yes you are absolutely correct
Because of my inexperience in antennas and relative nomenclature
I have been unable thru the years to communicate efficiently
with those that are knoweledgable in the field.
This has bred fraustration every year when I try to make a fresh start
in openly discussing my antenna. Now, just when my determination
started
to wane I read Termans explanations regarding 'resonant circuits.'
Now at last I have a vehicle to travel on of which every one is aware
so that
the antenna subject can be 'contained' and with the same nomenclature
used to explain what I have (or at least what I think I have). It is
this that gives me hope that we or I will be allowed a fresh start.
In TERMAN'S type nomenclature I have a RANDOM length dipole
radiator which for the most part can be considered a UNTUNED radiator,
since in the main there is reactance present and thus it is generaly
UNTUNED. At this point I really don't care how one feeds such a thing
tho I chose to use a delta feed.
I then joined (COUPLED) it to a TUNED circuit which in my case was a
LOOP
antenna with a additional variable capacitor for TUNING. I then
COUPLED both circuits together such that at least a third of the TUNED
circuit was in direct contact with the UNTUNED circuit. When using
this co-joined antenna I found that
the best of LOOP antennas came into play without the hinderance of
inefficiency
and narrow bandwidth e.t.c., especially so when I migrated towards top
band.
When I migrated the other way with respect to frequency the UNTUNED
circuit took on more of the role in radiation by using the TUNED
circiut to enact a phase change on the dipole such that radiation
lobes became mainly IN PHASE.
This is what I found, but I had no way of knowing or recognizing what
was an error and what was not (faulty connectors ?)
Now for the first time I believe I have explained it well enough so we
can have a reasonable discussion based on TERMAN and with the past put
aside.

This is what I am hoping for ! What does Terman and the Gurus and
others say
should have taken place in using such an antenna over varied
frequencies ?.
Doc, what do you think I should have expected with such an arrangement
that I experimented with ?
Best Regards
Art KB9MZ.....XG

4181. Re: Characterizing a commercial trap

Message-ID: <asvt7teft1@knossos.btinternet.com>
Source record: 129620

It is impossible to determine anything about anything which is made from unknown materials.

But for an electrical device which appears to be made from ordinary materials an ordinary practical person would just put the expected amount of power into it, hold his palm against it, and if after a minute or two it was no more than pleasantly warm he would declare it suitable for the purpose intended and sign the certificate. 'Measurements' completed satisfactorily!

As for estimating loss for a given Tx power, in ordinary L and C traps including distributed C in the coil, I would use program TRAPDIP.

This program estimates trap loss at the two different resonant frequencies of a trapped dipole. Greatest uncertainty is due to coil Q.

For coaxial distributed-C traps programs COAXTRAP and COAXRATE would be useful.

As for power handling capability it is necessary to know the thermal properties and limitations of all the construction materials, plus the greatest expected ambient temperature, plus details of radiative and convective properties, wind velocity, etc.

Clearly this would involve 100 times more work than the rest of the program put together for hardly any more return on the effort than could be obtained from guess work after looking at it for a minute or two.

A safety factor is always involved when specifying power handling capabilities.

As for yagi traps, if they are what I think they are then the power handling capability is limited by the breakdown voltage.

Ian, your question is too vague to answer unless the required degree of accuracy is stated. You havn't said at what altitude above sea level the traps are required to work.

4184. Antenna Grounding Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-08 17:23:46 UTC
From: Robert11 <rgsrose@tiac.net>
Message-ID: <asvvdope1@slb5.atl.mindspring.net>
Source record: 129623

Hello:

Still wondering about this, and let me re-phrase my original question, and ask for any other opinions on.

Am trying to figure out what makes the most sense for me regarding protecting
my receiver from (possible) static charges, or induced voltages via the aerials due to nearby lightning strikes.

Hope the following question is reasonably clear; will be happy to clarify any portion of my question, if not.

I do listening only, and have a Discone pretty high up in the attic.
Also a random length wire running around the attic sides for the below 30 MHz stuff.

Not too worried about direct lightning hits; mainly concerned about induced voltages picked up by the
aerials from nearby lightning, or normal static buildup, and led to the receiver.

Right now, I disconnect the receivers two aerials when I'm not using them.
Undoubtedly the safest approach, but frankly has become a bit of a pain; particularly for the Discone's coax.

Have been thinking about adding a two position antenna switch, probably for each aerial, as a way around the inconvenience.
Am wondering about how to connect them, if I do go this way.

Let's say I have the switches Common terminal to the aerial, and the radio to the "A" tap. Nothing connected to "B".

The switches (haven't actually seen them) seem to ground the Unused tap when not being used.
If I put the switch to "B", this grounds the receivers input, which seems fine, and what I would want.

But now concerning the unused tap "B", which would then be fed by the Common going to the aerial:

If I permanently ground this tap, I would imagine there could be 0 Voltage buildup, but high currents flowing from a "nearby" lightning strike.

If I allow it to float, there could be 0 Current flow from a nearby strike, but very high voltages would be possible, with the possibility of arcing somewhere along the path (also static buildup would not be bled off).

What's the best approach?

Also, any opinions on the Daiwa, Alpha, or MFJ switches sold by Universal?
Quality, etc.

Much thanks,
Bob

As a two port device, input to output. He didn't say it was an antenna trap, which didn't occur to me until now. Still, I see no reason to measure current.

Bob,
What you suggest will certainly work. Rather than
have the disconnected antennas 'float', why not use the
'other' terminals of the switches go to ground? By the
way, I would look for the cheapest switches I could find.

Tom,
The 'A99' has no gain on 11 meters, no matter
what the manufacturer says. Of course, that just
depends on what antenna the manufacturer compares
their antenna ~to~. Since most antenna makers
compare their antenna to a beer can in the the
back yard, they find that their antenna has some
remarkable gain characteristics.

Lee,
You're asking what the loss is of a PL-259
and a barrel connector. Something on the order
of .25 db per connector is the 'going' guess,
but, that's all it is. Depends on who makes
the connector and how well they are installed.

Reg,
You're right, I exaggerated too much in that
statement. What I should have said was that
you have to know what assumption the manufacturer
made when they gave the rating. Since the coax
maker can't know what the conditions of use are,
they can only make guesses as to how much power
their cable can handle in their own controlled
circumstances.
By the way, RG-8x can handle 1000 watts all
day long if the circumstances are right (been
there, done that, don't need the 'T' shirt).
Same thing for RG-58u and 500 watts.
'Doc

PS - You gotta know the circumstances.

When you see any gain listed for a simple antenna that is physically the same or shorter than a 1/2 wave dipole then the listing of dBi the i stands for IDIOT.
It is all advertising junk.

A 1/2 wave antenna will have a small ammount of gain over an isotropic antenna. The isotropic antenna is just a mathmatical modle and is very hare to make one in real life.

Dick I should have resisted the temptation to enter this thread.
My point solely was to show how the use of percentages alone can
distort things.

If an area had a 300% increase in policeman killing i.e increase of
one to
three, and another place only had a 30% of similar killings it would
appear that you don't have to be a rocket scientist to decide where to
live. But if the information that the 'paltry' 30% represented an
increase from thirty killings to forty then those that extoll the
lesser increase in percentages alone for purposes of debate could get
a rude awakening. I went to a public meeting once regarding a new
housing development. A farmer decried the extra draw on well water
that would occur with all the extra wells. The response was that the
developer was well aware of the well water problem and thus well
digging would be restricted to one drilling for every TWO residences,
50%
of what would normally have been expected The farmer sat down
apparently satisfied,
With an ommision of facts and misleading the farmer the developer
'won' the debate.
I consider such action to mislead as a very cheap victory but I may
well of misunderstood and thus I now retreat.
Best Regards
Art

Art, KB9MZ wrote:
"What do Terman, the Gurus, and others say should have taken place in using such an antenna over varied frequencies?"

Cecil shows a dipole can be satisfactorily operated off-resonance. Cecil`s matching scheme is very different from Art`s, but there`s more than one way to skin a cat.

I infer that Art expects antenna gain from using a small loop at his doublet feedpoint and this loop shares a side with part of the doublet. This loop mounting causes it to share a plane with the doublet.

Terman shows why there is no gain from this configuration tn the usually desired directions.

On page 907 of Terman`s 4th edition (1955) of "Electronic and Radio Engineering" are found typical loops.

Terman writes of small rim-type loops:
"No energy is radiated in a direction perpendicular to the plane of the loop because the radiation in this direction from any section of the loop is always cancelled by radiation from a corresponding section on the diametrically opposite side of the loop carrying current in the opposite direction."

On page 867 of Terman`s same book he writes:
"An observer in direction P3 (on the axis of a straight-wire antenna such as a dipole) likewise receives no radiation (from the straight-wire antenna) because each elementary length of antenna radiates zero field in the direction of its axis."

So, if the vertical loop shares a side with a dipole, the loop radiates in every direction except a horizontal broadside. Broadside horizontal and low angle radiation might give some gain.

The vertical loop sharing a side with part of a straight-wire antenna does aid radiation from the straight-wire towards the zenith and towards the earth. It also radiates towards ends of the straight-wire which normally have nulls. This only helps in special applications.

It's stamped from flat stock and shaped like a parallelogram to compensate for the slight offset of the two driven element legs. If you're making a hairpin out of wire, start with one about 5" long.

I have just got into making antennas. I have made a couple for 2 meters. They work ok but my question is one I can not find on the internet. I am making some yagi beams and I am confused about the driven element. Some have the driven in two parts and therefor the feed line is one each of the elements... some have the driven in one peice centered on the boom. These antennas say nothing about where or how to connect the feed line. Can someone shed some light on this subject. I have been just cutting the driven in the middle on all my projects. Is this what I should be doing?

BTW, I am getting the ARRL book but thougt I would try to get this question answered first.

Thanks

Well, how about this one?

According to the International Crime Victims Survey conducted by the Dutch Ministry of Justice, England, Australia and Wales consistently won the dubious honors of having the highest burglary rates and the highest rates for crimes of violence such as robbery, assault and sexual assault in the 17 top industrialized nations.

Conducted in the year 2000 with interviews involving 35,000 individuals, the survey was summed up as a shocker in the British press. The Guardian reported the study "shows England and Wales at the top of the world league with Australia as the countries where you are most likely to become a victim of crime."

Of course they do, Steve. If you think energy doesn't add as simple scalar values, you are missing something. What you are missing is the re-reflected energy in the constructive interference. Why do you choose to ignore that energy? Do you actually believe that energy is destroyed during wave cancellation? It's a simple yes or no question, Steve. If you don't answer, it will be apparent that you don't want anyone to know your answer.

>>There's no valid way to add two scalar values to get more out of it than you
>>put into it. You seem to have invented supersuperposing of powers.

> In the superposition of multiple vector voltages and currents, it is the
> multiple individual vector voltages and currents that add, not the multiple
> individual scalar powers.

That's what you say and you are wrong as can be seen from your magic energy machine at: http://www.qsl.net/w5dxp/magic.gif Would you mind changing that diagram to make it correct? As far as I can determine, it is exactly what you believe.

> The same is not true for the square of the magnitude of the voltages, which
> is the scalar power. I.e. The vector voltage Vtotal = V1 + V2 and
> |Vtotal|^2 can be greater than |V1|^2 + |V2|^2. Its also true that
> |Vtotal|^2 can be equal to or less than |V1|^2 + |V2|^2.

Absolute nonsense for transmission lines and leads to a violation of the conservation of energy principle. You simply have not included all the voltages or all the energy. Why do you choose to keep two of the four products of superposition and throw the other two away?

> For this reason, superposition of individual scalar powers cannot be used to
> determine the total scalar power resulting from the vector addition of two
> vector voltages and currents.

You are the only one trying to superpose powers, Steve. I know better than to do anything except add them using scalar math. The energy equation must balance. If yours doesn't, you have left something out. What you have left out of your voltage equation is the two voltages involved in the destructive interference. What you have left out of your energy equation is the energy

involved in the destructive interference. If you would include the terms
you left out, you wouldn't have any problem violating the conservation
of energy principle but you would be forced to admit that everything except
P1 is re-reflected energy.

> In vector superposition, Ptotal is not equal to P1 + P2, unless the
> associated vector voltages, V1 and V2 are 90 degrees out of phase.

That's exactly right because your term, 2 Sqrt(P1) Sqrt(P2) is not P1 and
P2 at all. It is re-reflected power caused by constructive interference.
I am preparing proof of that fact on my web page. In fact, P1=75W is the
only power out of the entire Ptot=133.33W that is not re-reflected.

Power traveling toward the source is reflected power. Power traveling toward
the load is either unreflected power or re-reflected power. There is no power
traveling toward the source. Therefore, all the power is traveling toward the
load has to be unreflected power or re-reflected power. There is simply no
other possibility.

Thanks, that explains the statement. As others have pointed out, it's not easy to measure antenna trap loss, which can be quite different on each band, and depends strongly on what band combination the antenna accommodates. But, provided that the L, C, and equivalent R, or the Z at each frequency, are known, loss can be predicted quite accurately by modeling.

Art, thanks for the explanation. I have two questions.

1. You say you've improved the efficiency of a common dipole. A common dipole is nearly 100% efficient, so no improvement would be noticeable. Why do you think the very small improvement that it's possible to achieve is important?

2. You say that the "radiation lobes became mainly in phase". What does this mean in terms of gain and pattern?

The driven element in two pieces is probably a dipole. In this case this element is connected through a symetrical (balanced) line.
If the driven element is a single piece (same length), it can be connected with a gamma match and a coax cable. This is not the only solution.

>scalar values, you are missing something.

If you combine two 100 watt each transmitters that are on different
frequencies, into the same
line and put a Bird watt meter in that line, it will read greater than
the sum of the two transmitter
powers. This is with the line feeding a flat 50 ohm load. It could
read as high as 400 watts
depending on the phase relationship of the two frequencies involved.

Richard is well aware of this in AM broadcast transmitters. A 100 watt
carrier modulated
100% with a single tone produces two side bands of 25 watts each.
Adding the powers
together would give you 150 watts total. But to get the true power out
you must first add the
voltages of each signal to compute the power. Doing so gives a total
power out of 400 watts.

>73's
>Richard Clark, KB7QHC

The answer then, as it remains inferred by your reading of Terman, is that yes, there is more than a dB difference. In fact there is an average 1.57dB LOSS across 6 amateur bands, on each band, when compared to a simple doublet.

Are Hams willing to trade in their antennas for this design if they know they are going to lose performance? If there is some compelling and simple alternative to offset the loss perhaps. In this regard, Cecil's method of tuning an "un-tuned" radiator is just such a case, and this method does not lose gain. Cecil's method is simply that top list of results which shows an average of 1.57dB GAIN in comparison for every band.

In short, and barring contrary evidence, Cecil's method is simpler to tune (making the un tuned radiator wide band), has less components in the air (two simple wires), and has more gain (1.57dB average) across HF. For a "stagnant" design, it is hard to beat at any level.

Is there a formula or something like that to determine the gamma match
placement or do you just adjust it for SWR?

When you get the book look up "gamma match" and "delta match". You
might even find them on the web. And you could always turn the driven
element into a folded dipole.

RE: Earlier posts below...

If the wattmeter is designed to measure RMS power, it will show 200 watts in the 1st scenario below, and 150 watts in the 2nd (assuming the modulation is sinusoidal). A typical example of such a meter is the HP 435 series.

An inline wattmeter using the typical diode element (Bird etc) will rectify both carriers to produce an output based on the two original frequencies and their mixing products. They are not designed, or suitable for measuring power in multi-freq RF systems.

I think the higher the better in general although there are probably cases where a lower antenna could be better for shorter paths. The higher antenna will have a much better local coverage as far as the ground/space wave. The higher antenna will have lower ground losses. For dx, the higher antenna should be better in almost all cases, despite possible higher angles per certain heights in wavelength. The higher antenna will open the band earlier, and close later than the low antenna. Usually about a hours worth each way. The only drawback I see is a possible reduction of strength to closer stateside signals. You see much the same effect when comparing beams at high and low heights. If I had to choose, I go the higher one anyday. As far as the other post mentioning that the Force antenna recomending no higher than 5 ft, and keeping the feedline at right angles, I'm not sure. I haven't seen that antenna. But that leads me to believe they must have a decoupling problem with that antenna. Near the ground is the last place you want one of those antennas. Their advice doesn't really make sense, and would probably lead me to avoid that antenna until I knew what the problem was. It's fairly evident that the feedline must act as part of the antenna if they advise that info. Any half wave antenna I've ever built could be mounted at any height with little worries about excess feedline radiation. And I always elevate mine. Most all I've built were ringo types. I've never had severe common mode problems with that type of matching device. "gamma loop" feed. It decouples the feedline well enough to normally have no problems elevating. MK

They do exist ! I use the 500C made by Austin Custom antennas in N.H. His call is K1QIZ and his antenna are super. Now they are NOT 5/8 wl but I have tested these antennas and compared them to the normal antennas (being the normal 5/8 wl) and found them to perform better. The reason is they are center fed with a special feed system and the take off angle is on the horizon as compared to most ham antennas that you buy

Hope this helps

Tom,
The 'A99' is a 1/2 wave antenna. If you compare a 1/2 wave
to a 1/2 wave at the same frequency, they should be the same,
right? That means there is no gain, or it has a gain of '1'.
Yes, I'm sure there's no gain.

If we read 100 watts forward and 10 watts of reflected power from a
given load we assume
90 watts gets dissipated in the load. How much power is the
transmitter putting out? 90 watts?
What happens to the 10 watts of reflected power? Does it get
re-reflected back to the load. If
so how much power is the load really dissipating?

Now put an isolator at the transmitter with a load on the third port.
Feed the same load as
above. If the transmitter puts out 90 watts we should read 100 watts
forward and 10 watts
reflected. How much of the reflected 10 watts gets dissipated in the
load on the isolator and
how much gets re-reflected?

Does the antenna have a balun now? 4:1, or 1:1? It might have a faulty
balun if so. The A4 beam I have uses a 1:1 coax choke. Using rg-8,
it's 8 turns wound with a 6 inch diameter form. Don't use foam coax
for these. Those should be good dimensions for any tri band beam. MK

> depending on the phase relationship of the two frequencies involved.

So does that mean that you can get 400 watts out of two 100 watt transmitters? Of course not. You have made a measurement error. We are not discussing two waves of different frequencies. We are discussing coherent waves. Does a Bird wattmeter make the same mistake with coherent waves?

Steve says you can take TWO AND ONLY TWO coherent waves and superpose them to obtain more energy than the sum of the two energies in the independent waves. That is a clear violation of the conservation of energy principle. There's no way to combine TWO AND ONLY TWO waves of 75W and 8.33W to obtain a wave of 133.33W. Steve agrees that there are four quantities predicted by superposition but he says two of them are canceled. He doesn't seem to realize that ENERGY CANNOT BE CANCELED. That's what our argument is all about.

Steve is apparently unaware that interference can cause re-reflection of power. He says the only things that can cause 100% re-reflection of power are a short-circuit, open-circuit, or pure reactance. But of course, destructive interference in one direction in a transmission line causes a reflected constructive interference energy wave in the opposite direction. If the destructive interference involves two reflected waves, as it does in Steve's example in his article, then the constructive interference results in a re-reflected energy wave, by definition. That makes about a dozen of Steve's assertions in his article false.

Steve says that total re-reflection of reflected energy doesn't occur at an impedance match point in a transmission line. No reflected energy reaches the source. There are only two directions, toward the source and toward the load. So where does the reflected energy go if it doesn't reach the source and it doesn't reach the load? Does Steve know about some secret black hole that is sucking up all the reflected energy from every antenna system on the planet?

Thankyou.
Many have said the same.
I am hoping that holding to the same terms as that used by
Terman will make it easier for all. Hopefully my question is
now quite clear as we now have a blueprint to follow as to
what one could expect from such an antenna.
If I get derision for even experimenting with such a setup
where now everything is to be done by computor, then so be it.
Again, do you have any insight as to what one should expect?
You certainly do not have to wait on a guru before voicing
an opinion
Regards
Art

> --
> cheers, CAM http://www.qsl.net/w5dxp
[snip]

Do not forget that not only SWR but also "reflected power" is a
calculation
and not a measurement!

The Bird Wattmeter "calculates" the reflected power, it does not measure
Watts
directly.

To do so the Bird "Wattmeter" utilizes a simple passive internal analog
computer
circuit which calculates the so-called "reflected voltage" B = V - RI from
the
actual measured voltage V and current I observed at a single point on the
line
[Hence, it cannot even observe any standing waves!] and then it displays
this voltage
indication "B" on a meter scale which is marked in Watts, the scale markings
being a
further [nomographic] analog computer which takes into account the implicit
squaring of
the voltage and a division by the reference resistance R to arrive at Watts.

That's by definition. It may be putting out 100W and dissipating
the 10W. But that's still just a *net* output of 90W which is
how it is defined.

> What happens to the 10 watts of reflected power? Does it get
> re-reflected back to the load. If
> so how much power is the load really dissipating?

The load dissipates 90% of the incident power.

> Now put an isolator at the transmitter with a load on the third port.
> Feed the same load as
> above. If the transmitter puts out 90 watts we should read 100 watts
> forward and 10 watts reflected.

Nope, we won't. If the isolator is dissipating all the reflected power
and the transmitter is putting out 90 watts, we will read 90 watts
forward and 9 watts reflected.

> How much of the reflected 10 watts gets dissipated in the
> load on the isolator and how much gets re-reflected?

Ideally, all the reflected 9 watts gets dissipated in the isolator.

"Richard is well aware of this in AM broadcast transmitters. A 100 watt carrier modulated 100% with a single tone produces two side bands of 25 watts each."

Bingo!

Countless times I`ve set the modulation to 100%. The antenna system current at the common point rises by 22.5%. R-F volts do the same thing but aren`t so conveniently monitored.

The "common point" is recognized by the FCC as a known resistance of the transmission line sort. It is where power output is determined.

1.225 squared is 1.5, the factor by which power delivered to the antenna system increases with 100% moulation.

Best regards, Richard Harrison, KB5WZI

But it is a calculation supported by measurements. A laboratory signal generator equipped with a circulator can make the same measurements and obtain the same results if the SWR meter is being properly used. I'm not saying that an SWR meter cannot be abused. One must understand the necessary and sufficient boundary conditions to obtain valid results.

> The Bird Wattmeter "calculates" the reflected power, it does not measure

But a wattmeter that actually measures the watts directly gets the same results as the Bird. Do you run your transmitted signal through a wattmeter that actually measures the watts directly, Peter? If so, you must love QRP. :-)

Have only tried it sitting in the usual bucket of cement. Have had it
for nine months and not bad considering it's small size. I feel a
linear amplifier would help greatly as so often I hear the DX but they
donb't hear me with 35 watts. The makers say to mount it on the
ground but you hear of guys using it from their balcony , well off the
ground.

Well all would like "extra gain" but first I would like a better
understanding of what one should expect based on what Terman says.
Starting off with just 'gain' statements usually means that all
discussion come to an end.

>
> Terman shows why there is no gain from this configuration tn the usually
> desired directions.

Well again I don't want to get down on the gain question as it always
gets down to more gain with respect to what! I think I need a bit more
understanding before that should be debated if ever.
>
> On page 907 of Terman`s 4th edition (1955) of "Electronic and Radio
> Engineering" are found typical loops.

> opposite direction."

I would assume he is speaking of a loop antenna alone where my
concerns are
it's characteristics when coupled to another radiator. I was thinking
that certain characteristics may well change. I might add that I did
change the
loop to one that would radiate in the same plain as the rest of the
radiator
per your prior suggestion

>
> On page 867 of Terman`s same book he writes:
> "An observer in direction P3 (on the axis of a straight-wire antenna

> and low angle radiation might give some gain.

Well it did appear that at some capacitor settings the nulls could
fill in where in other cases the radiation was a sharp figure 8 but
then I do know if I was just misreading or misinterpreting things.

>
> The vertical loop sharing a side with part of a straight-wire antenna
> does aid radiation from the straight-wire towards the zenith and towards
> the earth. It also radiates towards ends of the straight-wire which
> normally have nulls. This only helps in special applications.

Humm.. So what is your interpretation of what Terman suggests one
should expect
when using such a combination over a broad spectrum range ? I
mentioned earlier
that changes did occur with respect to frequency range and I might add
that directivety held up quite well across the frequency span but
again, I would
prefer to get a better idea of what Terman says I should expect from
those that have a better background than I, as well as other ideas to
put into the mix.
Some people have the ability to read such a tract by Terman and thus
state
exactly what one should expect without concern to what other people
say or
without concern to odd experimental findings.

Best bet is to get some literature on antennas. ARRL antenna handbook is a good choice. As is the one by William Orr. Then start experimenting once you have a basic background. But the main thing to remember is......its ALL MAGIC.

Does it matter if they are coherent? Two voltages on the transmission
line add together don't they. If they are not coherent then the
resultant voltage will depend on the phase relationship. If
two equal coherent voltages are present don't you get the sum of the
two?

So you are saying that with 90 watts going to the load, the load will
only absorb 81 watts and reflect 9 watts? (The watt meter shows 10
watts reflected.)

And what happens to the 9 watts or (10 watts) that is reflected?

This seems to contradict what others say about how much power the load
dissipates.

So with an isolator in the circuit the watt meter will read the
correct forward power but the load

will not accept all of the forward power?

just type in ocxo in ebay, titles and descriptions..
also look for an HP 5328A with the high stabilty which is the HP 10811 high stabilty OCXO, one of the finest on the market...
Another optio is to look for a Racal 1992 with high stability oscillator..
However I I think you'll find a better deal on an HP 5328A..
there's several rith now andheres a list:
http://search.ebay.com/search/search.dll?MfcISAPICommand=GetResult&SortProperty=MetaEndSort&ht=1&query=5328a
good luck

You also may want to look at getting a HP Z3801A which is a GPS receiver that disciplines a HP 10811 oscillator in the same box. Can get these for between $250-300...add a 48VDC power supply and an antenna any you've got a great shop 10MHz reference.

See "www.realhamradio.com" for details.

> Why do you think the very small improvement that it's possible to
> achieve is important?

When a dipole is cut for a particular frquency then it would be
difficult to say it could be beaten. If a dipole is used for several
bands then for some of these bands the PHYSICAL length is redundant.
If one can remove the redundancy
then one has gained efficiency with respect to the actual physical
length provided.
Said another way, an element in a multiband dipole has a length that
is dictated
only by a single band and is wasted when the 'dipole' is used on other
bands.

>
> 2. You say that the "radiation lobes became mainly in phase". What does
> this mean in terms of gain and pattern?

If one has a multiband dipole as described above and one was tempted
to use
all the physical length regardless of frequency used, the current
pattern would exceed 180 degrees which is not desirable. If one found
a way to have all current flow to stay on the 'positive' (additive?)
side i.e. in phase without cancellation then performance can be
improved beyond that of using the 'cut length' alone and leaving the
rest of the radiator (from a trap outward)as redundant.
The use of the word "mainly" is not to discount radiation occurred
during a phase change that may or may not be desirable. Hopefully that
will suffice for the moment the dwelling on gain.

>

Regards
Art

Roy. If you don't mind I would like to answer the above privately.
I am concerned that when we talk 'gain' I will be pulled down into a
hole because of past writings. This is why I have posed this question
around Termans writing about a circuit that is the same as my antenna
but admittedly smaller. So that those who are familiar with him and
the antenna subject could provide their observations. In other words
this thread is not about me it is meant to be a request for a analysis
of what Terman says so that I may gain a better
insight about my experimentation . If I don't get a Email of objection
I will respond first thing in the morning. For other readers I hope
you understand that I am not being evasive or rude, I just want to
keep the
discussion civil and within the boundaries of my question otherwise
all will be lost.
Thank you for your consideration and also for your participation.Every
morsel of insight can be the last bit of the jigsaw puzzle that makes
the picture complete.
Regards
Art

Dale,
I don't think there's any 'rule', more of a
try this many, then a couple more, or a couple
less. Six or eight turns sounds like a good
place to start. The diameter should be what
ever the coax will fold into without forcing it,
about 6-8 inches wought to work fine (about the
size of a 3# coffee can).
'Doc

PS - Or, download Reg's program about chokes and
plug in the numbers.

You're using "efficiency" in an uncommon way. That's undoubtedly
contributing to your communication difficulty. It sounds like you mean
"gain", or the amount of energy concentrated in a particular direction.
This is different from efficiency. Since you have Terman, look in the
index under "efficiency" and read his definition carefully. Then, if
you're really interested in communicating your ideas, use it only in
that way.

No, it won't at all. You've been bemoaning that people haven't jumped on the bandwagon to praise your antenna. And you've accused "gurus" (unnamed, except for me by implication) of everything from contradicting Terman to ignoring revolutionary ideas. Yet you still haven't presented any quantitative indication of just what your antenna accomplishes, except lengthy and vague ramblings. Sorry, as an engineer, I'm not impressed by the vague ramblings. I am impressed by measured or even modeled performance data, to allow a quantitative comparison to the technology you claim your antenna is superior to. Apparently you have none of the latter. Until you do, there's no way to tell what you may or may not have accomplished, and you'll continue to be frustrated by the lack of enthusiam you get. Without data, your antenna is in the same class as the CFA, the patented faster-than-light-speed antenna, and all the other antennas someone has thought to be the best thing since canned beer.

You won't get much respect for your invention until you can talk about gain, bandwidth, or some other property of your antenna in terms that can be measured or compared to others. That's simply the only way any objective person can figure out what it is that you've got. Engineers are much harder to convince than patent examiners, since we ultimately have to produce something that works.

Gary, K4FMX wrote:
"What is the difference in antenna lne voltage with the modulation and without modulation?"

I gave the 122,5% current as increased with a tone modulating the carrier 100%. I noted that 1.225 squared is 1.5. This indicates the 50% power increase with 100% modulation. It also shows that since power is the product of volts times amps, 1.225xvolts is needed with the 1.225xamps to reach 1.5xpower.

The current of an amplitude modulated amplifier does not on average vary during the amplitude modulation process. This is evidence that the amplitude of the carrier is independent of the modulation. A spectrum analysis is even more convincing. The sideband displays grow and shrink with modulation while the carrier remains constant.

The carrier and its sidebands combine vectorially to produce the familiar modlated carrier display on an oscilloscope.

100% modulation squeezes the carrier to zero and doubles its value on the other direction of the modulation cycle. This produces two sidebands from a single modulating frequency. Power in these two sidebands together with the carrier is 50% greater than the carrier power alone. 1/3 of the total energy is in the sidebands. 2/3 of the total energy is in the carrier.

Suppose you have a 100% modulated 1000 watt carrier and it is impressed on 1000 ohms. The carrier will produce 1000 volts. Each sideband contains 250 watts and produces 500 volts across 1000 ohms. When carrier and both sidebands coincide in phase, their voltages add to 2000 volts on one side of the peak and add to zero volts on the other side of the peak.

Gary, K4FMX wrote:
"What is the difference in antenna line voltage with no modulation and with modulation?"

I tried to respond but fat fingered the wrong key. Don`t know if the mangled response will appear or if it is lost in cyberspace.

Short answer is the current and voltage both increase by 22.5% with 100% modulation. With no modulation you don`t have the 22.5% increase. The reduction when 100% modulation falls to 0% modulation is the reciprocal or 100/122.5 or 0.816 times the 100% modulated voltage or current.

Best regards, Richard Harrison, KB5WZI

> two?

Not from a Bird wattmeter if they are traveling in opposite directions.
The Bird wattmeter uses vector addition to subtract out one of the waves.
It will read either forward joules/sec or reflected joules/sec depending
on where the slug is set.

Steve is correct when he says a wave with the voltage and current in phase
contains an energy equal to V*I joules/sec. The conservation of energy
principle will not allow anyone to get any more or less energy out of
that wave than V*I joules/sec. The voltage equation must balance, the
current equation must balance, and the energy equation must balance.

Nobody can add two and only two 70.7V at 1.414A waves to get 141.4V at
2.828A. If one could do that, one could get 400W out of two IC-706's.

Which gives a peak envelope power of 4000 watts. Greater than the sum
of the power in the carrier and the side bands. The only way to
determine peak envelope power is to first add the
voltages and or currents. It can not be obtained by directly adding
the powers together.

The wattmeter does not show 10 watts reflected if the forward power is
90 watts. It shows 9 watts reflected. 10% of the forward power is
reflected.

> And what happens to the 9 watts or (10 watts) that is reflected?

It is either totally reflected, partially reflected, or not reflected
at the transmitter. In the real world it is hard to tell unless you
have an antenna tuner in which case the reflected power is totally
re-reflected. You might understand the following better.

90W XMTR---tuner----100W forward, 10W reflected----Load

> This seems to contradict what others say about how much power the load
> dissipates.

What does? The load dissipates forward power minus reflected power.

> So with an isolator in the circuit the watt meter will read the
> correct forward power but the load will not accept all of the
> forward power?

The load accepts only 90% of the forward power. A correct wattmeter
will read the correct forward power whether it is 100W or 90W. If
the forward power is 100W, the load will accept 90W and reflect 10W.
If the forward power is 90W, the load will accept 91W and reflect 9W.

That's much too broad a statement, Art. G5RV selected his 1.5WL
on 20M for the cloverleaf pattern. I love the multi-lobed patterns
I get on the higher bands with my 130 ft. dipole. A resonant dipole
gives a couple of ~6dBi lobes. I get four lobes with 10dBi each.
For some purposes, that is more desirable than a resonant dipole.

But a Bird watt meter does do just that. It does not distinguish which
direction the voltage is coming from, only the current direction. That
is why the Bird watt meter reads higher forward
power when there is reflected power present.

That is also why the Bird watt meter will read 100 watts forward and
100 watts reflected when
there is an open or no line connected to the meter output side. There
is no current to be read, only voltage. That is why it tells you there
is 100 watts when there is really no power flowing.

You are missing the question or I am missing the answer. We started out with a 90 watt
transmitter and a watt meter inline feeding a load. The watt meter reading 100 watts forward
power READING and 10 watts reflected power READING.
Let's use the tuner at the transmitter as you show, then the watt meter then the load.

The question was how much power is dissipated in the load and how much power was re-reflected of the 10 watts that got reflected back to the transmitter (in this case back to the tuner). I am assuming that the watt meter reads 100 watts forward (rather than 90) because of the re-reflected 10 watts?

You say that "The load dissipates forward power minus reflected power". In this case that would be 90 watts dissipated by the load. If the load dissipates 90 watts and the transmitter is only putting out 90 watts, where does the 10 watts reflected power come from?

Now remove the tuner and add the isolator in its' place at the transmitter, still with 90 watts out of the transmitter.
Will the watt meter still read 100 watts forward and 10 watts reflected, or will
it now only read 90 watts forward and 9 watts reflected or something else.
In this case are you saying that only 81 watts will be dissipated in the load and 9 watts
reflected? Then the 9 reflected watts will be absorbed by the isolators load.

You seem to be saying that when the isolator is added that there will be less power absorbed by the load and less reflected power?

Seems to me it would be redundant period. The only thing that really
matters is efficient matching. Say with Cecils tuned line setup. Thats
efficient matching for all bands concerned. Better than most auto
tuners at the feedpoint I bet.

> If one can remove the redundancy
> then one has gained efficiency with respect to the actual physical

Well, maybe if you limit yourself to a coax feed. An tuner at the
feedpoint does the same job as your antenna design. I'm still
convinced that your loop that is attached to the dipole is nothing but
a matching device. It's not really acting like a loop anymore. It's
acting more like a delta match of sorts. Look at a picture of a delta
match. Then envision making it a rectangle instead of a triangle. It
will still do the same job. To me , it seems simple enough. And it is
a viable antenna if thats what you want. I don't see why this causes
you so much angst. Also, the modeling I did on that antenna seemed to
confirm my thinking behind that antenna. As far as gain, there should
be little if any difference from a equal length dipole fed in any
other manner.

Hi Art,

It is alright if you want to separate the issue of gain from drive point Z, bandwidth or the like, but you dig a fresh hole when in the space of 3 sentences you abandon the gain line only to pick it up again with:
>that would radiate in the same plain as the rest of the radiator
Radiation must eventually get around to gain otherwise you have nothing to say - and certainly less about Z. The two are unrelated except through the circumstance of luck. If this annoys you, you make your own bad luck through poor terminology and intermingling of unrelated topics.

Now, as to the epiphany of Terman. That is all good and well, too bad you didn't read all the postings that tried to inform you of this since last summer when many offered. Simply review the archive to the many postings that you left unanswered about the nature of coupling between your elements. Most often they were described as variants of loose, critical, and over coupling to reveal characteristics of narrow bandedness to double humped resonances with broad bandedness. You will find exactly these issues discussed and illustrated in Terman in the chapters surrounding the section you recite.

[snip]

No, of course I don't.

And I don't use a Bird "in-line" while "on-air" either. In fact the only
meter I use while
"tuning" my HF antennas is the reflected power indicator built into my
transceiver, which
I tune for a "dip" so that the transceiver is seeing 50 Ohms like it should.

My point was that there is probably a good reason why Bird does not have SWR
readouts on their voltage reading, 50 Ohm, "Wattmeters".

Perhaps it is because the Bird meters do not actually "read" or "measure"
standing waves.

Adam--

Sometimes, there's nothing like "reality" for solving a practical problem. When I designed this antenna for MFJ, I calculated somewhere around 5" for the hairpin. I then used a shorting bar and two parallel strips of aluminum to determine the exact length. Given the myriad of variables that were operating, that approach made the most sense to me--and it took about 10 minutes to resolve. Good luck with it.

Hi

What's confusing me is that I was always under the impression that maximum power can only be transferred if the Zout from one stage was equal to the Zin of the next. That being the case, then how could all of the output power be transferred to the load in a mismatched condition? What am I missing? Isn't reflected power just that, power not absorbed by the load being reflected back to the source? Isn't this what damages circuitry?

Unless I'm totally missing something, I have to answer the original question this way:

The forward power measurement would be: TX power + Reflected power, and the load would dissipate TX power - Reflected power, the reflected power would be dissipated in the source or along the transmission line, if it were imperfect.

Isn't this the case?

Which is very little. .3 db??? I think, comparing elevated 1/4 wave
ground planes vs elevated 1/2 wave verticals on VHF where the height
in WL is a few waves. In the real world, the degree of feedline
decoupling would probably determine the winner. MK

okay guys
according to the website www.universal-radio.com here is what they call
an A99

The Solarcon A99 is a half wave over a quarter wave variable mutual
inductance antenna for 10 to 17 meters. It features the Solarcon twin
ring Adjust-A-Match system to obtain the optimum SWR. Simply raise the
rings to the raise the frequency or lower the lower rings to lower the
resonant frequency.

since it is more like a J-pole wouldnt it have about 3db of gain?

If the transmitter is matched to the load presented to it at the tx end of the coax, all of the power reflected by the mismatched antenna will be re-reflected back towards the antenna when it reaches the Tx. All of the Tx power will eventually either be radiated by the antenna or disipated by the feed line loss. If the feedline loss is fairly low to begin with (as in a typical HF installation) then very little total power will be lost in the feed line - the vast majority of it will eventually be radiated by the antenna.

If the transmitter output circuitry is not properly matched to the load presented to it by the tx end of the feed line then all of the power generated by the tx will not couple into the feedline (and thus not be shown as forward power on the meter). This may cause excessive disipation in the final tx stage and may be what some are contributing to "power being reflected back into the transmitter" and causing damage. Most modern solid state output circuits now have a fold-back circuit to reduce the generated power and protect the output stage when the load is not correct. The old tube circuits had tune and load controls to permit the operator to match the output to a variety of load impedances.

4288. AM Peak Power

Newsgroup: rec.radio.amateur.antenna

RE: Previous clips below the * * * *

Peak envelope power is related to zero volts/amps/watts, your choice, and the respective maximum of that unit -- not the peak-peak excursion of the composite RF waveform as viewed in the time domain (a transmitter does not produce "negative power").

There is sometimes confusion of average and peak values when discussing this subject. Following is a paste from a spreadsheet showing the various derivations and values for the conditions stated.

GIVEN:

VSWR = 1:1
1,000 ohm Impedance (R)
1 kW Unmod Carrier Power

and

Avg Volts = (1 + Mod Index) * SQRT(VSWR * Unmod Avg Carrier Pwr * R)
Peak Volts = Avg Volts * 1.414
Peak Power = Peak Volts^2 / R

THEN, for SINEWAVE AMPLITUDE MODULATION

Modulation % 0 100

Steve wrote:
"Isn`t this the case?"

You`ve got it!

A load which accepts 90% of the energy presented, accepts 90% of the once rejected energy on the second go around. 90% of 10% leaves 1% of the first rejected energy, as twice rejected energy, to lose another 90% on its 3rd go around after which there is 0.1% of the first pass incident energy to have a fourth go at the load.

The continuous toll on the energy presented is 90% in this example, whatever the age of the the energy.

Gary,K4FMX rote:
"If the load dissipates 90 watts and the transmitter is only putting out 90 watts, where does the 10 watts come from?"

Who`s on first? It comes from current and previous reflections. The transmitter has to produce only an insignificant bit of power in excess of 90 watts to permit an accumulation of reflected power to total 10 watts. This power is not delivered by the transmitter at the instant it is being displayed. Like bags on an airport carrousel, the power was previously deposited and is just going around and around.

Best regards, Richard Harrison, KB5WZI

> power when there is reflected power present.

The forward power is actually there. That's why there are greater losses
in coax when the SWR is high. Please sit down and do the vector math
graphically for yourself. Assuming all the boundary conditions are met,
adding the current vector to the voltage vector yields a signal proportional
to the actual forward power. Subtracting the current vector from the voltage
vector yields a signal proportional to the actual reflected power.

> That is also why the Bird watt meter will read 100 watts forward and
> 100 watts reflected when
> there is an open or no line connected to the meter output side. There
> is no current to be read, only voltage. That is why it tells you there
> is 100 watts when there is really no power flowing.

There is energy flowing, i.e. power, and there is current flowing. If we
are dealing with 50 ohm coax, the forward voltage will be 70.7V and the
forward current will be 1.414A. The reflected voltage will be 70.7V and
the reflected current will be 1.414A. The peak (loop) voltage will be 141.4V.
The peak (loop) current will be 2.828A. You can measure all of this. That
current heats up the coax. Why do you think there is no energy flow?

I don't know of any RF engineers who haven't, in one way or another, been
seduced by the steady-state model. In reality, true steady-state doesn't
exist for AC since the voltage and current are continuously changing. RMS
values are averages invented by the human mind to make things easier for us.

> reading.

Nope, your description didn't include the tuner. The tuner allows an impedance match that blocks any reflected power from being incident to the transmitter. Your example allowed reflected power to flow into the transmitter. That is a very complicated situation.

> You are missing the question or I am missing the answer. We started
> out with a 90 watt

> reading 100 watts forward
> power READING and 10 watts reflected power READING.
> Let's use the tuner at the transmitter as you show, then the watt
> meter then the load.

The tuner makes things very simple if it is tuned for a match.

> The question was how much power is dissipated in the load and how much
> power was re-reflected of the 10 watts that got reflected back to the
> transmitter (in this case back to the tuner). I am assuming that the
> watt meter reads 100 watts forward (rather than 90) because of the
> re-reflected 10 watts?

With the tuner tuned to a match, we can measure zero reflected power incident upon the source and 90W being supplied by the source.

> You say that "The load dissipates forward power minus reflected
> power". In this case that would be 90 watts dissipated by the load.
> If the load dissipates 90 watts and the transmitter is only putting
> out 90 watts, where does the 10 watts reflected power come from?

It is injected into the line during the transient buildup to steady-state conditions. That 10 watts is joules/sec supplied by the source that has not reached the load. At any instant, the 90 watts out of the source is not the same 90 watts that is being accepted by the load. The transmission line is a delay line.

> Now remove the tuner and add the isolator in its' place at the
> transmitter, still with 90 watts out of the transmitter.
> Will the watt meter still read 100 watts forward and 10 watts
> reflected, or will
> it now only read 90 watts forward and 9 watts reflected or something

> else.

With the isolator dissipating all the reflected power, the wattmeter
will read a forward power equal to the source power, i.e. 90 watts.

> In this case are you saying that only 81 watts will be dissipated in
> the load and 9 watts
> reflected? Then the 9 reflected watts will be absorbed by the
> isolators load.
>
> You seem to be saying that when the isolator is added that there will
> be less power absorbed by the load and less reflected power?

Exactly. The isolator is absorbing 9 watts that is never available to the
load. There will be less power incident upon the load and therefore less
power reflected.

Art, KB9MZ wrote:
"If a dipole is used for several bands then for some of these bands the PHYSICAL length is redundant."

Physical length scales to electrical length.

Since we are using Terman, please look at Table 23-1 on page 871 of his 1955 edition. Directive gain is a function of wire lngth. Ganted, energy becomes re-directed at wire lengths considerably in excess of 1/2-wavelength. Redundant may not be the best description of excess wire as Cecil noted, he prizes contacts from lobes not perpendicular to the wire.

Note also in Table 23-1, the tiny elementary dipole has a 1.5 gain ratio with an isotropic. A 1/2-wave wire in space has a 1.64 gain ratio over the isotropic. The extra gain of the 1/2-wave antenna is not redundant if more is better.

What you are missing is that all the output power is transferred to the
load but the maximum available output power is not transferred to the load.
The "output power" is defined as whatever power is being output under
any conditions. The "maximum available output power" is the power output
under matched conditions. There's a big difference.

Source record: 129541
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,sci.electronics

The rule you quote about matching is true only under a particular set of conditions. Unfortunately, it's often quoted as being a universal Truth, which it's not.

IF you have a source with a fixed impedance, AND adjust nothing but the load impedance, then the maximum load power dissipation will occur when the load impedance is the complex conjugate of the source impedance. If the source and load are purely resistive, this means that the load impedance equals the source impedance.

So let's look at a particular case: A 141.4 volt RMS voltage source in series with a 50 ohm resistor, connected to a load resistor whose value we can vary. We'll find that, sure enough, the maximum dissipation occurs when the load resistor is 50 ohms. Its dissipation will be 100 watts. The voltage source has to produce 200 watts, since another 100 is dissipated in the source resistor. If we consider the efficiency as the ratio of the power in the load to the power produced by the voltage source, it's 50% when matched. Note, though, that although this is a good circuit for explaining what's happening, it's not necessarily a good model of a transmitter. Many transmitters exceed 50% efficiency when producing their maximum power, and may or may not be matched under this condition.

Now, between the source (that is, voltage source + source resistor) and the 50 ohm load let's connect a half wavelength of lossless 450 ohm transmission line. The line's SWR is 9:1. The forward power on the line is 278 watts, and the reverse power is 178 watts. What's the power dissipated by the load? It's 100 watts, just as before. And the voltage source is still producing 200 watts, and the source resistor is dissipating 100 watts. This is a simple voltage divider circuit you can completely analyze in a couple of minutes. The forward and reverse power on the line are of no consequence at all -- all that counts is the impedance *seen by the source*. In this case, it's 50 ohms. For that matter, we can make the transmission line impedance anything we'd like, and get any amount of reverse power we'd like, from zero (when the line impedance is 50 ohms) to anything. Yet the voltage source, source resistor, and load resistor dissipations will remain unchanged.

But suppose we change the load to 450 ohms, leaving the line impedance at 450 ohms. The power in the load is now only 36 watts, the line's reverse power is zero, and the source resistor dissipation is 4 watts, and the voltage source is producing 40 watts. Hmm. The efficiency is now 90%! So the condition for maximum power transfer isn't the same condition as for maximum efficiency. Anyway, next put a tuner at the

source end of the line to transform the 450 ohms looking into the line, to 50 ohms. The load (and source resistor) dissipation will increase to 100 watts. On the line, the forward power is 100 watts and the reverse power is zero. Now move the tuner to the output end of the line, leaving the adjustment the same. You'll find that the load power is still 100 watts, the source resistor power still 100 watts, and the voltage source is still producing 200 watts. But the line's forward power is now 278 watts and reverse power 178 watts. You see, the only thing that's important is the impedance *seen by the source*. Reverse power has nothing to do with source or load dissipation.

One last thing to think about. Instead of fixing the source impedance at 50 ohms and varying the load impedance, try fixing the load impedance and varying the source impedance while leaving the voltage of the voltage source unchanged. What value of source impedance will produce the maximum power in the load? Hint: It's not 50 ohms.

Roy Lewallen, W7EL

Doesn't a half-wave vertical have the same gain relationship to a
quarter-wave vertical as a full-wave dipole has to a half-wave
dipole, i.e. about 2 dB?

Heh....not likely. YEARS ago, we checked gas pump electronics in a chamber....I volunteered the old Clegg FM27B I had as a 144 mhz source. 600 mW is not likely to cause anything except inattention at the pump. Legal liability only....i.e., "it is electronic and may cause a spark, so we need a warning sign." I'm more worried about causing a spark via static electricity than by cell phone.

Could it be zero ohms? :-) That's what the power companies do - go
for maximum efficiency instead of maximum power transfer. Way back
when, someone proved that power companies would probably never
exist because they would burn themselves up trying to achieve
maximum power transfer.

Strange you are having so much RF with a balanced antenna. Is the
RF entering on the outer braid of the coax? Is the SWR okay? I'm
wondering if you might have a bad connector at the antenna...

Try a choke balun at the antenna feedpoint, and one where the coax
enters the shack. You can use a ferrite bead kit from Palomar if you
don't want to wind a coaxial style choke.

You presented such in your magazine article, Steve, and you left out half of the energy components predicted by superposition. Why should I allow your error onto my web page uncontested? Just add whatever you need to to my diagram to make it correct. I tried to accurately reproduce your concepts. So if there's not 50 watts of extra power, please indicate exactly where the extra 50 watts comes from in:

http://www.qsl.net/w5dxp/magic.gif

Hint: if you draw another arrow into the superposer and label it "50 watts from constructive interference", your conservation of energy problem will go away.

Reg, does a virtual 50 ohms *cause* the V/I ratio to be 50 or
does the virtual 50 ohms *result* from the V/I ratio being 50?

You could be an exception, but virtually all RF engineers I
know, at one time or another, engage in petitio principii, i.e.
they know the answer so they assume the proof.

> Unity gain compared to a 1/2WL dipole. How about dBi?

> cheers, CAM http://www.qsl.net/w5dxp

Cam:

As explained in the very first response to the original post, "gain" depends on what you use for a reference of comparison.

Yes, a dipole has gain over an isotropic radiator. To quote from the ARRL antenna manual: "An infinitely thin 1/2 wavelength dipole has a theoretical gain of 2.14 dB oiver an isotropic radiator (dBi). Thus, the gain of an actual antenna over a 1/2 wavelength dipole can be referred to isotropic by adding 2.14 dB to the measured gain."

Most of us think of "gain" as "gain over a dipole", since a dipole is a basic ham antenna and an isotropic radiator is not. Manufacturers base their claims of gain on all kinds of comparisons...it was that ambiguity that led the ARRL to ban gain claims from antenna ads in QST many years ago. Other publications are not so concerned about truth in advertising an allow disreputable manufactures to make all kinds of wild claims of gain.

Heh, heh... true. But measuring standing waves is only useful for single frequency systems at *relatively* high frequencies.

Slotted lines don't work very well for determining mis-match, reflected power, etc... at very low frequencies,
at DC or over broad bandwidths.

For that you need different/better instrumentation.

> For some purposes, that is more desirable than a resonant dipole.

Cecil, I am not an expert of any kind so you should expect what you
call broad statements from one such as I. You bring the G5RV subject
up which I know is your personal delight but we have different
aproaches.I also 'can' get multi lobes which you enjoy and probably
with the similar gains. My aproach is for a antenna that is rotatable
so directionality is important to me tho not to you.
I could not possibly rotate a 130 foot dipole so I cannot follow the
excellent path that you have provided. But I sure could use your
technical knowhow
as to what one could expect if one expanded Terman and resonant
circuit teaching
on audio when it is expanded to larger things such as antemnas. If one
had the knoweledge and the comprehension of such things they could
help me to shed some light on multi frequency use,directivety and how
I seem to think that I have salvaged the desirable properties of the
loop antenna yet leaving it's faults behind. For some reason this
antenna gives me the use of all bands just like many people who wrote
for 73 magazine who somehow had connected to the house gutter by
default which has confused them. Now I have found some writings
that can be called fixed laws of nature but my brain cannot
comprehend all so that I can build on it. Cecil, could you put my
antenna sayings, claims and what have you and read what Terman said as
if you were going to follow his sayings with respect to a antenna ?
Your writings and experiments show that you are an independent thinker
and your insight would be so valuable in promoting debate....The
subject is more than just gain or the rantings of me.
Respectfully
Art

OK, OK... but... I'm just a simple DC engineer and I admit I was once
seduced by a steady-state model.

I had a run in with Jim Beam and Jack Daniels and I couldn't resist leaning
on her lovely steady shoulders.

She was kinda shy and had one bad eye... but her VSWR was a perfect 1.0 even
though she was mis-matched
and had increased losses in her transmission media under the mis-match!

Hmmm,

Sounds a lot like invoking constructive and destructive interference to make an energy equation balance.

Since neither of these components is observable in the system under debate, it would appear that you have been hoist with your own petard.

By not observable I mean more than simply not measurable due to inadequate instrumentation. It is not possible to measure the interferences you rely upon without perturbing the system under examination. This is a classic problem throughout science and engineering.

It is not acceptable to invoke circulators, perfect laboratory sources, and so on. Each of these adjuncts would completely change the system under examination.

There are many examples (perhaps an infinite number) in science where alternate analytical approaches will yield the same physical conclusions. Short of philosophical discussions there is little to support the "best" choice of one approach over the other.

One of the beauties of science and math is that, for example, solutions based on forces and momentum give exactly the same answers as solutions based on conservation of energy.

Steve chooses to use vector addition of voltages and currents; you choose to use conservation of energy. Steve does not worry explicitly about the balance of energy; you choose to create an artifice to allow you to not worry explicitly about the addition of voltages and currents.

At this point it is merely arguing about the number of angels dancing on a pin.

If you fix the load resistance at 50 ohms and vary the source resistance, zero ohms provides both the best efficiency (100%) and the maximum power dissipation in the load.

If the load is complex, Rl + jXl, the maximum load power will occur with a source impedance of 0 - jXl. Maximum efficiency (100%) will occur with a source resistance of zero, with any reactance.

Well, your drawing did not accurately reproduce my concepts. The drawing
has nothing to do with my concepts, so there is no point in trying to
correct it.

>So if there's not 50 watts of extra power, please indicate
> exactly where the extra 50 watts comes from in:
>

We disagree on the principles of superposition, specifically, the vector
addition of voltage and current.

Superposition requires that multiple voltages and currents applied to a
single impedance add as vectors. I.e. two vector voltages, V1 and V2,
applied in series to an impedance (like two forward voltages in Zo), add as
Vtotal = V1 + V2. You have stated that you disagree with the vector
addition of voltage.

All that happens in transmission line as the system transitions to the
steady state is following: In the forward direction, the total forward
voltage increases through the vector addition of the multiple forward
voltages (Vtotal = V1 + V2 + V3 + ...). As the total forward voltage
increases, the total forward power increases as a function of the square of
the magnitude of the total forward voltage. In the rearward direction, the
total rearward voltage decreases through the vector addition of the multiple
rearward voltages (Vtotal = V1 + V2 + V3 + ..). As the total rearward
voltage decreases, the total rearward power decreases as a function of the
square of the magnitude of the total rearward voltage. The law of
conservation of power is satisfied at all times because the total power
flowing into the junction is equal to the total power flowing out of the
junction.

At this point, I think that you are unnecessarily trying to account for
"extra power" based on a fundamental misunderstanding of the superposition
process. The forward voltage increases, the forward power increases

appropriately. The rearward voltage decreases, the rearward power decreases appropriately. At no time is the law of conservation of power violated in this process.

Take care. This subject has taken far too much time and bandwidth for me.

Steve VE9SRB

4327. SWR Calculations/In-line Wattmeters

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-09 17:30:24 UTC
From: Richard Fry <rfry@adams.net>
Message-ID: <Hq4J9.31159$5P3.2166233@newsfeed.slurp.net>
Source record: 129566

RE: Pastes below

SWR can be calculated directly from the output values of the forward and reflected couplers, using a microprocessor. Some of the fancier Bird meters do that, I think.

But no matter how the SWR calculation is determined (directly, or by charts), it is limited by the directivity of the forward and reflected couplers. Therefore this approach produces decreasing accuracy for low SWRs, because the output of the reflected coupler contains a progressively higher proportion of forward power, which pollutes the true value of the reflected sample.

The typical in-line wattmeter OEM says to use a 10:1 ratio for the forward and reflected slugs. With a full-scale reading from the forward element, that 10dB ratio means that the smaller element shows an equivalent SWR of ~1.93:1 at full scale. Then the calculation is being made with two values having 5% accuracy, each, AT BEST -- probably worse, because most often the meters do not read full scale in a typical application. That 5% spec also depends on a 1:1 load termination, which isn't often the case. So clearly the SWR calculations for low values get rather meaningless, and probably not worth doing with this approach for anything less than about 1.5:1.

The company from which I retired makes TV/FM/AM broadcast transmitters, and we often had cases where a customer would "measure" the output of his new transmitter with an in-line wattmeter and see an apparent discrepancy from the factory test data. But the transmitter power meter had been set quite accurately for that operating power and frequency during final test, using an optimized load and calorimeter. The transmitter metering was the more accurate of the two, but sometimes that didn't stop the buyer from "calibrating" the tx against his Bird meter.

R. Fry

>>> Do Bird make SWR meters, ie., a meter with a scale

Hi Richard,

I will ask Gary's question too. However I will use the original quote
from Cecil that brought it:
>
> If the isolator is dissipating all the reflected power
>and the transmitter is putting out 90 watts, we will read 90 watts
>forward and 9 watts reflected.
>
Where is the 9W coming from? Is it read from a SWR meter that comes
AFTER the isolator? This smacks of deliberate misuse of equipment to
leverage an argument. If Cecil thought it strange that Gary should do
so (place the SWR meter after the isolator) he would have challenged
him then for an explanation (there was no challenge). If Cecil
thought that this was an error of Gary's and continued on, he didn't
say so; as such that defense has evaporated. If Cecil thought that
this was an error of Gary's and wanted to draw out the error in terms
of an erroneous result, THAT error has been compounded by Cecil's own
for failure to reveal his agenda.

Frankly, Gary asked good faith questions and Cecil is playing the
thick cowpoke, aw shucks, boot toe scrubbing the dirt stereotype. I
am not impressed that any further dialog will find a legitimate answer
that serves any interest other than this Mutt'n'Jeff routine played
out with a drawl.

I've watched Gary reel out a series of excellent questions that are
finding some painted into a corner. These posted reactions have all
the quality of those so floor limited dancing from one foot to another
hoping that will dry the paint through the illusion of progress.

Hi Richard,

Thanks for the interjection of sanity. I know that I need to jump out of this endless loop. Sometimes that's easier said than done - as you are well aware from my previous "this is my last post" statements - its an aspect of my personality that I need to work on. As I mentioned to another NG participant - we are no longer permitted to dual with swords or pistols - the best we have available is the keyboard.

In any event, thanks for the comments. I will be signing off on this conversation.....

GPS receivers only receive signals, they do not transmit them. I have looked and looked over the internet and I still can not find one instance of a cell phone (or similiar device) causing an accident. This leads me to believe that the regulation has less to do with the safety of the plane and more to do with the possible congestion of the cellular networks when people at 30,000 feet are tying up several hundred towers.

I agree about the gain should be refferanced to a 1/2 wave dipole in free space. Saw where one antenna maker was using an antenna modling program and also calculating the gain with the fround reflection added to it to give more gain..... That was at VHF where yo normally mount the antenna high enough the added gain due to the ground reflection or takeoff angle will have little effect.

Advertised gain numbers have almost no meaning. What is also interisting is how a 5 element antenna on one frequency can have a couple of more or less gain than an antenna of the same number of elements on another frequency , all by the same maker.
Either one is very efficient or the other is very poor !!

It is the notion of reflected power itself which causes the confusion. Best to erase it from the imagination and return to square one. All can be clarified without resorting to black magic. KISS. There's no point in trying to solve problems which didn't exist before reflected power entered the vocabulary.

Here's another trap to avoid. If the generator impedance is Zg = R+jX and load impedance XL is also R+jX, ie., generator impedance is equal to load impedance, then maximum available power is NOT transferred.

It is essential not to use Z when only R is meant. That bad habit, which almost everybody in ham radio suffers from, causes much confusion, is the hidden root of many arguments and has lost friends.

The driven element is not too important to a beam. What is important is that it will have an impedance depending on how it is coupled to the other elements (electrically). You have to have an idea of wht the impedance of the element will be and what the feedline impedance will be before you can calculate anything.
There are many ways to match the antenna driven element to the beam. For some 3 element beans and under, it is possiable to get a low swr by attaching the coax to the split element like a dipole. The patern may be offset to one side if this id done.

It doesn't matter. Every receiver has some sort of an oscillator which,
albeit very weak, *could* interfere with the aircraft's sensitive
navigation and control systems. Especially if every passenger fired up
one or more of those.

There really shouldn't be any cellphone caused accidents since by the
time cellphones came about, it was a well established fact that RF was a
potential hazard in the airplane environment. As for the the congestion
thing, the FAA doesn't give a rat's ass about that anymore that they
cared that CB users would be able to contact people across the borders
due to the increased range. RF in any form is simply not allowed in the
planes - transmitters or receivers.

Point is, an average 1/4WL vertical doesn't have gain over
an isotropic radiator. Therefore, a vertical dipole has
gain over the average 1/4WL vertical which has a gain of
zero dBi.

wrote:

|RE: Pastes below
|
|SWR can be calculated directly from the output values of the forward and
|reflected couplers, using a microprocessor. Some of the fancier Bird meters
|do that, I think.
|
|But no matter how the SWR calculation is determined (directly, or by
|charts), it is limited by the directivity of the forward and reflected
|couplers.

Among other things. Such as the VSWR of the connector on the output of
the instrument + any adapters, etc....

|Therefore this approach produces decreasing accuracy for low SWRs,
|because the output of the reflected coupler contains a progressively higher
|proportion of forward power, which pollutes the true value of the reflected
|sample.

Yep, the better the thing is that you're trying to measure, the harder
it is to do it accurately. But the directivity vector can be
determined if you have a sliding load handy <g>.

|
|The typical in-line wattmeter OEM says to use a 10:1 ratio for the forward
|and reflected slugs. With a full-scale reading from the forward element,
|that 10dB ratio means that the smaller element shows an equivalent SWR of
|~1.93:1 at full scale. Then the calculation is being made with two values
|having 5% accuracy, each, AT BEST -- probably worse, because most often the
|meters do not read full scale in a typical application. That 5% spec also
|depends on a 1:1 load termination, which isn't often the case. So clearly
|the SWR calculations for low values get rather meaningless, and probably not
|worth doing with this approach for anything less than about 1.5:1.
|
|The company from which I retired makes TV/FM/AM broadcast transmitters, and
|we often had cases where a customer would "measure" the output of his new
|transmitter with an in-line wattmeter and see an apparent discrepancy from
|the factory test data. But the transmitter power meter had been set quite
|accurately for that operating power and frequency during final test, using
|an optimized load and calorimeter. The transmitter metering was the more
|accurate of the two, but sometimes that didn't stop the buyer from
|"calibrating" the tx against his Bird meter.

What is an "optimized load", the same one the customer is using?

Art, do you have a web page? I am a visual person and often get absolutely lost in word descriptions including yours. I have little idea what your antenna looks like. If you could post a diagram of your antenna, a picture would be worth a thousand words. Or send me the diagram and I'll be glad to post it.

If I had to guess what your antenna looks like it would be (in fixed font) but not to scale:

```
-------------------------------------------------------------------------
+------------------------+
| |
| |
| |
+-----------FP-----------+
```

> Your writings and experiments show that you are an independent thinker

Art, I am such an independent thinker that I have never, to the best of my memory, cracked open a copy of Terman - not that I haven't tried to find one. The extent of my modest RF library is Johnson, Ramo/Whinnery, Skilling, Balanis, Schaum's Outlines, "Reference Data for Radio Engineers", and ARRL/ham publications.

:-) The other day someone posted a wench for sale over on rec.radio.swap.
I asked what was her name, what did she look like, and how old was she.

Peter, you ask what is the difference between DC and AC. The difference
is infinite. The first derivative of DC is zero. The first derivative of
an AC sine wave of any frequency is a cosine wave of the same frequency.

it is my opinion that there are plenty of reports floating around of both
proven and suspected interference with aircraft systems which show up for
a few seconds and once corrected/eliminated by the crew (cabin or cockpit)
do not occur.

yes, the cell-companies dont like having lots of their ground stations
reporting what the signal strength of a phone at 35000feet is as the whole
width of florida can in theory be covered at only 10,000feet.
(see people taking calulators out now... 1.23 square root....)

can you imagine what it would be like to have 1000 phones active and being
traced by huge chunks of the network ?
now multiply again by another 400 and you get a rough and probably
slightly high approx of how many phones *could* be in air at 1600hrs
Colorado time. thats alot of tracking to be done and in one country.

airlines will always put the safety of their passengers ahead of any
cellular phone network. if they dont - accidents happen.

The constructive and destructive interference components are predicted
by the superposition principle. I guess you either accept the superposition
principle or not. Steve throws away half of the energy components predicted
by the superposition principle so he obviously doesn't accept it.

> By not observable I mean more than simply not measurable due to
> inadequate instrumentation. It is not possible to measure the
> interferences you rely upon without perturbing the system under
> examination. This is a classic problem throughout science and
> engineering.

It's not quantum physics, Gene. There is so much energy, we can tap
off a mite without changing things very much.

> There are many examples (perhaps an infinite number) in science where
> alternate analytical approaches will yield the same physical
> conclusions. Short of philosophical discussions there is little to
> support the "best" choice of one approach over the other.

If you have your choice between two explanations, one violates the
conservation of energy principle and one doesn't, which would you choose?
My argument and Steve's argument yield the same measurements but do not
yield the same physical conclusions.

> Steve chooses to use vector addition of voltages and currents; you
> choose to use conservation of energy. Steve does not worry explicitly
> about the balance of energy; you choose to create an artifice to allow
> you to not worry explicitly about the addition of voltages and currents.

That's an absolutely false statement, Gene. I use both vector addition of
voltages and currents *and* the conservation of energy principle. My vector
voltage equations add up. My vector current equations add up. My scalar energy
equation balances. Steve's vector voltage equations add up even though he omits
two of the values. Steve's vector current equations add up even though he omits

two of the values. Steve's energy equation doesn't balance because he omits two of the values. So which explanation is the best?

Referencing Steve's Fig 1, redrawn on my web page at:

http://www.qsl.net/w5dxp/sbfig1.gif

The superposition principle predicts the following:

Pfwd1 = 100W = Pfwd1(1-Rho^2) + Pfwd1(Rho^2) = 75W + 25W = P1 + P3

Pref2 = 33.33W = Pref2(Rho^2) + Pref2(1-Rho^2) = 8.33W + 25W = P2 + P4

P1 = 75W and P2 = 8.33W are the same as Steve's P1 and P2

P3 = 25W and P4 = 25W are the powers involved in the interference pattern which Steve labels, "rearward traveling waves 1 and 2".

Reference Dr. Best's Magic Energy Machine at http://www.qsl.net/w5dxp/magic.gif

The voltages and currents associated with the four energy components predicted by the superposition principle are:

P1 = 75W = 61.24V at zero degrees and 1.225A at zero degrees
P2 = 8.33W = 20.41V at zero degrees and 0.408A at zero degrees
P3 = 25W = 35.355V at zero degrees and 0.707A at 180 degrees
P4 = 25W = 35.355V at 180 degrees and 0.707A at 180 degrees

Steve agrees with the above four energy components. Why does he choose to omit two of the components from his voltage, current, and energy equations?

The actual voltage equation is:
Vtot = 61.24V at 0 deg + 20.41V at 0 deg + 35.355V at 0 deg + 35.355V at 180 deg
Vtot = 81.65V (Steve and I agree on this value)

The actual current equation is:
Itot = 1.225A at 0 deg + 0.408A at 0 deg + 0.707A at 180 deg + 0.707A at 0 deg
Itot = 1.63A (Steve and I agree on this value)

The actual energy equations are:
Ptot = 61.24V^2/50 + 20.41V^2/50 + 35.355V^2/50 + (-35.355V)^2/50
Ptot = P1 + P2 + P3 + P4 = 75W + 8.33W + 25W + 25W = 133.33W

Ptot = 1.225A^2*50 + 0.408A^2*50 + (-0.707A)^2*50 + 0.707A^2*50
Ptot = P1 + P2 + P3 + P4 = 75W + 8.33W + 25W + 25W = 133.33W

P3 and P4 are the energy components involved in the wave interference that are completely ignored by Dr. Best. He calls them "rearward traveling waves 1 and 2" and says that they cancel. Can the energy in those waves cancel? Of course not! That's the 50 joules/sec that Steve is missing in his energy equation. So why does Steve choose to ignore the other two energy components predicted by the superposition principle?

P3 = 25W = 35.355V at 0 deg and 0.707A at 180 degrees
P4 = 25W = 35.355V at 180 deg and 0.707A at 0 degrees

Note that P3 and P4 each have their voltages 180 degrees out of phase.
That makes them REFLECTED POWERS. When this energy is canceled in the
direction of the source by destructive interference, the result is a
constructive interference wave of RE_REFLECTED POWER in the direction
of the load. Now we see the reason why Steve needs to ignore and hide
this re-reflected energy. If he admits that the missing energy is indeed
re-reflected energy, about a dozen of his article statements are rendered
false. In fact, P1=75W is the only power in the system that is not re-
reflected.

<flames off>
<respect on>

given that most local-oscillators are (whats the term)
high-side-injection (or something like that) and given that the vhf nav band is right above the vhf broadcast band, there is a high probability that an ordinary radio could be tuned to a frequency that is X MHz (e.g. 10.7) away from a valid vhf navigation frequency.

e.g. listen to KXYZ on 101.6 => 100.6 + 10.7 = 111.3
(assumption: KXYZ is on 100.6 and is a valid fm broadcast freq)

111.3 happens to be a valid ILS frequency and IF (big IF) its the active one for a particular airport then you might have problems landing because someone has a radio on in the cabin.

i have personal experience of a personal-stereo-radio that could blot out other broadcast stations by using its local-osc.

and remember it doesnt need to blot out the frequency, just cause enough inteference for the airborne radio to reject the detected info off the radio signal.

nowadays, vhf nav radios must be 'fm broadcast interference suppressed' capable as per some directive that came out about 3 years ago.

when in an aircraft - safety comes first. (even on the ground)

Translation: That picture is worth a thousand words and shows exactly
what is wrong with Dr. Best's concepts. Dr. Best cannot re-draw it
without admitting that he choose to ignore half of the energy components
predicted by the superposition principle.

> We disagree on the principles of superposition, specifically, the vector
> addition of voltage and current.

Nope, we do not, Steve! That's just one of your strawmen. We agree perfectly
on the results of the vector addition of voltage and current.

Your voltage equation:
Vtot = 61.24V at 0 deg + 20.41V at 0 deg = 81.65V at 0 deg

My voltage equation:
Vtot = 61.24V at 0 deg + 20.41V at 0 deg + 35.355V at 0 deg + 35.355V at 180 deg
Vtot = 81.65V at 0 deg

Our results are *identical*, Steve. Where do we disagree on the vector
addition of voltage? The question is: Why did you choose to leave out
half of the voltage components predicted by the superposition principle?

> Superposition requires that multiple voltages and currents applied to a
> single impedance add as vectors. I.e. two vector voltages, V1 and V2,
> applied in series to an impedance (like two forward voltages in Zo), add as
> Vtotal = V1 + V2. You have stated that you disagree with the vector
> addition of voltage.

I have NOT stated that I disagree with the vector addition of voltage nor
have I any disagreement with you on the vector addition of voltage. I have
stated that multiple times. You seem to have the desperate need to spread
such falsehoods. One wonders why? See above. Our results are *identical*!
Where I disagree with you is on your superposition of energy to obtain more
than the sum of the energy components.

> All that happens in transmission line as the system transitions to the
> steady state is following: In the forward direction, the total forward
> voltage increases through the vector addition of the multiple forward
> voltages (Vtotal = V1 + V2 + V3 + ...). As the total forward voltage
> increases, the total forward power increases as a function of the square of

> the magnitude of the total forward voltage.

Yes, that's exactly what happens so why did you leave out V3 + V4 in your voltage equation and V3^2/Z0 + V4^2/Z0 in your energy equation? - you know, the two voltage terms that when squared, are exactly proportional to your missing energy in the system? The forward power increase is constructive interference, i.e. RE-REFLECTED energy.

> In the rearward direction, the
> total rearward voltage decreases through the vector addition of the multiple
> rearward voltages (Vtotal = V1 + V2 + V3 + ..). As the total rearward
> voltage decreases, the total rearward power decreases as a function of the
> square of the magnitude of the total rearward voltage.

Yep, and that power decrease is called destructive interference of REFLECTED waves. It results in constructive interference in the other direction. That, my friend, is RE-REFLECTION in action! In fact, P1=75W is the only energy in your example that is not re-reflected energy. P2+P3+P4 = 58.33W is RE-REFLECTED energy. P2, P3, and P4 were all once moving toward the source. They wind up moving toward the load. That's nothing except re-reflection.

> At this point, I think that you are unnecessarily trying to account for
> "extra power" based on a fundamental misunderstanding of the superposition
> process.

Of course you must say that because if the "extra power" were accounted for, everyone would understand that it is actually RE-REFLECTED power and a dozen of your article statements would be wrong.

> The forward voltage increases, the forward power increases
> appropriately. The rearward voltage decreases, the rearward power decreases
> appropriately. At no time is the law of conservation of power violated in
> this process.

It is violated by your equation 75W + 8.33W = 133.33W. You state that you are adding two and only two voltages. The energy associated with each voltage is V^2/Z0. If you try to get more than the associated energy out of those two and only two waves, you are mentally violating the conservation of energy principle. Why didn't you include all the terms predicted by the superposition principle? Why did you choose to leave out half of them?

>
> Roy Lewallen, W7EL
[snip]

Well... ahem, not exactly. I know it's not applicable to the typical
amateur radio HF transmitter,
but...

For the resistive case, reducing the source resistance to zero only
maximizes the load dissipation
when the source resistance is limited to positive values. In fact, the
maximum power dissipation
in the 50 Ohm load will be infinite and would occur when the variable source
resistance is adjusted
to be -50 Ohms [negative 50 Ohms], and in practice, this is just before "the
melt-down".

That said, there are indeed examples of real practical systems where
negative values of source
resistance are used and in these cases such use further increases power
transfer.

John,

The antennas with the split driven element generally use either a hairpin match and a 1:1 balun, or a beta match and a 4:1 balun. The latter is a lot easier, because it just consists of a 1/4 wavelength of coax. The one where the middle of the driven element is connected to the boom uses the gamma match, which is easier to homebrew, although I think a commercial beta match is more rugged. The gamma match uses a series capacitor, which is usually made up of a piece of insulated wire (coax with the shield stripped off) that slides inside the gamma rod. Other than the books, if at all possible look at a Cushcraft VHF beam.

I thought "unity gain" was a comparison to a 1/4 wave ground plane,
when comparing elevated verticals, or a 1/4 wave whip on mobile
mounts..? But no real matter...The difference is only about a third of
a db or so for the elevated antennas. MK

Hi Cecil,

You had a technical question to respond to, and you had a
characterization to respond to (and only after the repetition of the
technical question). Failing answering the technical question twice,
you choose here to fulfill the stereotype. Being wrong is not simply
an issue of mis-statement. Further, it was failure I addressed, not
right or wrong. The failure, through your choice alone, persists.
Resolve that technical question and the characterization disappears
and you are vindicated. You can then remonstrate me for ad hominem
and satisfy honor. Ignore the failure, and the characterization
persists instead.

Do I need to repeat the query a third time? That would obviously
cement the characterization... especially if it goes unresponded to.
It's still your choice which path to follow.

Hi Wes,

You probably lost a lot of readers on the last turn with that one. We are probably the only two (maybe a third, but he hasn't chimed in) in this group to have performed these techniques - for years.

There is no better schooling in this topic than having the scale of SHF to directly observe the entire scope of these effects at the bench. For those stuck below 1 GHz, I am sure they relate to it as the mysteries of belief and ignore it as religion.

Source record: 129501

Cecil,

It is not necessary to keep dredging up all of the detailed equations. We have all seen them ad nauseam. Your math is impeccable.

However, you are clearly missing the point or ignoring the point.

There is NOTHING OBSERVABLE that can distinguish between your model and Steve's model. You may choose to invoke interference if you wish, but that is simply an internal calculational detail.

By the way, there is no direct connection between superposition and interference. Non-linear systems can exhibit interference as well, even though they may not obey superposition.

For the uninitiated, the principle of superposition says:

If:
a system input of x1(t) produces an output of y1(t), and
a system input of x2(t) produces an output of y2(t)
Then:
An input of x1(t) + x2(t) must produce an output of y1(t) + y2(t).

If this does not occur then superposition does not apply for that system. No more and no less.

Can you find even one case in which Steve's calculation produces an incorrect physical result? You can change the load, Z0, line length, or any other parameter to your heart's content. The only thing you cannot do is add circulators, Maxwell demons, or any other schematic change.

This debate arises anew every couple of months, and the reason is simple. Both methods give the correct physical results. The rest is merely philosophy.

You may wish to simultaneously add and subtract some ficticious waves inside your model to make yourself happy, but Mother Nature doesn't care.

73,
Gene Fuller

> There is NOTHING OBSERVABLE that can distinguish between your model and
> Steve's model.

If that's true, how can Steve's statement that reflected power is not 100% re-reflected in a matched system, possibly be proven to be true? There is NOTHING OBSERVABLE that will make Steve's assertions true!!!

> By the way, there is no direct connection between superposition and
> interference. Non-linear systems can exhibit interference as well, even
> though they may not obey superposition.

Are you saying linear systems cannot exhibit interference? If not, your statement is irrelevant to this discussion.

> Can you find even one case in which Steve's calculation produces an
> incorrect physical result?

For the umpteenth time, the physical results are known so Steve wouldn't dare violate them. It is Steve's conceptual statements based on those physical results that are in question. For instance, in a lossless matched system, the only energy input into the system is from the source. ZERO reflected energy winds up reaching the source. All of the energy in the entire system winds up flowing toward the load. Therefore, all of the reflected energy in the entire system winds up flowing toward the load because none is flowing toward the source, i.e. all of the reflected energy in the entire system is re-reflected. This is such a simple concept that anything other than the above statement is simply a hoax perpetuated upon amateur radio. Steve dumps reflected power into a magician's hat and tells us that it has disappeared. He then taps three times with his magic wand and pours out 2 Sqrt(P1) Sqrt(P2) which coincidentally exactly equals the reflected power that he put into the hat in the first place. Then he tells us that it is not reflected power at all. He has not proven that statement to be true. Using his own model, I have proved that statement to be false.

> This debate arises anew every couple of months, and the reason is
> simple. Both methods give the correct physical results. The rest is
> merely philosophy.

Do you agree that every joule/sec of reflected energy winds up flowing toward the load? If not, where does it go? It doesn't reach the source, it cannot disappear, and it cannot stand still. If every joule/sec of reflected energy winds up flowing toward the load, a good dozen of Steve's statements are false. If every joule/sec of reflected energy doesn't wind up flowing toward the load, where does it go?

So here's a quiz for you: In a matched system where no reflected energy
reaches the load, the reflected energy:
1. Disappears from the system
2. Stands still
3. Flows toward the load (which Steve denies)

I can't think of any other possibility and the first two possibilities
are not valid. If the correct answer is '3', all the reflected energy
is re-reflected, by definition.

> current.

==========

Tam, you are quite correct. No need to measure RF current.

Knowing the trap inductance and frequency, with an estimate of coil Q it is ncessary only to measure RF volts to calculate watts dissipated in the coil.

But as we are interested ultimately only in the temperature rise above ambient, that can be measured directly with some sort of thermometer.

If you havn't a suitable sort of thermometer, temperature rise can be obtained from the increase in DC resistance of the copper wire in the coil itself. The temperature coefficient of resistance of copper (if I remember correctly) is +0.4 percent per degree Celsius.

Measurents of volts applied across the coil and its DC resistance can be made simultaneously, as indeed they should be. S'easy ! Been there, done that sort of thing - 45 years back ! Kelvin was doing it around 1850. That's why he invented his renouned bridge. When pushing back the frontiers of science, necessity is the mother of invention !

Trap manufacturers, of course, if they do anything at all, quite sensibly just do what hams do and apply a hands-on heat-test.

|Hi Wes,
|
|You probably lost a lot of readers on the last turn with that one. We
|are probably the only two (maybe a third, but he hasn't chimed in) in
|this group to have performed these techniques - for years.
|
|There is no better schooling in this topic than having the scale of
|SHF to directly observe the entire scope of these effects at the
|bench. For those stuck below 1 GHz, I am sure they relate to it as
|the mysteries of belief and ignore it as religion.

Hi Richard,

Yes one hasn't lived unless he's "calibrated" out the directivity
error on an HP8410 polar display by sliding a load and tweaking the
CRT X-Y position controls to center the circle on the screen.

In more recent times, a high grade cal on even an HP8510 called for a
coax sliding load. Five to eight sweeps at different positions and
the internal math calculated the center of the circle for you.

I'm out of the field now, but I believe the current trend is to
"electronic" standards that replace the open-short-load-thru, or
thru-reflection-line (TRL) fixed standards for routine calibration.

Regards,

Wes

I am looking for an omni-directional antenna for a receiver that picks up 433.92mhz transmission from miniature security tags. The tags are constantly moving (mostly installed in vehicles for automatic gate entry) and need to be picked up effeciently and quickly. The power output for the tags is listed as: -14 dBm, 72 db ï¿½V, 4300 ï¿½V/m, 38ï¿½W. The receiver has a female BNC antenna connection.

The tags should be receptive to over 115ft but no matter where we locate the receiver, the max is less than 30ft.

Any recommendations for manufacturers or types of antennas that might be suitable for my application is appreciated.

Wow! The Clegg FM27B has the distinction of emitting the most spurs of any radio I have ever tested. It attempted to use several mixers to produce the final output. Far too little filtering. The 27B is an ideal test source (in a shielded room) for EMC. [Fellow two miles from me had one. Every time he transmitted, about half of the repeaters, including commercial, would key.]

Love your story. 73 Mac N8TT

Actually, I seldom reference Terman, but the one I've got is his Radio Engineering, Third Edition. I've noticed in some earlier discussions that the text in some portions of the Third Edition is extensively revised in places, and recall one instance where it looked like he had significantly changed the meaning of what he was saying. So I recommend that anyone getting this book look for the latest edition available. I don't know how many editions there were altogether. I know Terman wrote at least one other big seller, but don't recall the title. I'm sure someone else will provide it.

well,
thats a tricky one. having taken one of these apart and actually figured
out the guts...
its nothing more than an end-fed halfwave antenna with a tunable
transformer at its base. it has more gain than a 1/4 wave verticle, but
not quite that of a dipole..

otherwise, its a pretty nice antenna for working local stuff.

If you disconnect the line from the watt meter then where is the power
going to flow? The meter will read 100 watts forward and 100 watts

reflected with very little voltage actually driving it. Is
there still 100 watts forward and 100 watts reflected?

Jerry wrote:
"So what is the name of Terman`s Book---?"

There are several. My first was "Radio Engineering" published in 1932 and again in 1937. I bought mine in 1947. Terman also co-authored a book on Measurements. Terman also authored several editions of "Radio Engineering Handbook". These were less pedantic and more for easy reference. My favorite is Terman`s "Electronic and Radio Engineering", fourth edition , from 1955. It is recent enough to include transistors.

Terman invented Silicon Valley by persuading Stanford, where he was dean of engineering, to lease out tracts on surplus school property to create an industrial park. Former students with fledgling companies, such as Hewlett Packard,
set up shops there, and the rest is just more history.

Shouldn't your "Average voltage" really be RMS voltage?

How do you come up with 40kw and 160kw peak power from a 1kw
transmitter?

I would come up with 8 kw peak power.

What I was referring to was "peak envelope power" which is 4 times the
carrier power with 100% modulation.

The point was that you can not just add the power in the side bands to
the carrier power to find
peak envelope power. No matter how you convert those powers. You must
first add the
voltages (or currents) associated with each together and then compute
the power.

There are several varients. I personally have both "Radio
Engineering", Third Edition (1947) and "Radio Engineer's Handbook",
First Edition (1943).

The flyleaf of latter lists his other books as: "Radio Engineering",
Fundamentals of Radio" and "Measurements in Radio Engineering."

Regardless of which one(s) you have, someone will quote from the one
you don't have <g>.

The problem with searching for "ocxo" is that you may miss a lot of ovenized oscillators this way. Not everyone who lists things on eBay does so with such explicit descriptions. Also, you won't find many with 10 MHz listed in the title, but it'll darn well be mentioned somehow in the text of the auction. Having bought three oven oscillators from people on eBay, I speak from my experience.

If the poster wants a NEW OCXO, places like Vectron are a good place to spend lots of money.

Close, but the side of the loop next to the dipole is part of the
dipole. A few months ago, he agreed this picture matched the antenna
he had in mind.
http://web.wt.net/~nm5k/loopole.jpg

I also redid your picture above to match the antenna. The "loop" wires
connect to the dipole. He also used a variable cap within the loop to
tune out reactance. Dunno, but I think he has invented the delta match
with square sides and added a cap for more tuning capability without
moving the tap points. The "loop" section acts no more like a loop
than the "triangle" of a delta match acts like a delta loop when
feeding a dipole. There is also no way to steer the pattern using such
a matching device if that is the intent. "Seems to be". You are not
using two elements. You are using a single dipole fed with a modified
delta match. If the loop were seperate, and both elements fed with
seperate lines, I suppose you could steer the pattern to a degree. But
being the loop is too small to have the desired "loop" ?? properties
on the bands in question, I don't think the performance would come
close to say parallel dipoles phased. Being the very small loop is not
too efficient once you match it to the line, overall antenna
efficiency would be less than a single dipole fed in an efficient
manner. I also don't have any Terman books, but in this case, I don't
think I really need one. I came to my conclusions on the design a few
months ago when I modeled it. So far no one is argueing with me, and

plenty here know way more than I do. MK

I completely agree that there are instances of Rf causing interference with
aircraft systems. I am sure that there are hundreds of first hand accounts
from pilots about this issue. I am just wondering what a .3 watt cell phone
is going to contribute to the issue. As far as your last statement, I just
wish they put out safety first period, cellular network or not.

p.s. I dont want to use my cell phone (or anybody else's for that matter) on
a plane because I enjoy the unavailability and relative silence

Ye gods, this is from a long time ago.
The stainless seizure myth is based on the problem that no one uses torque tools, and invariably over tightens stainless. I have literally thousands of pieces of stainless hardware in service, some for 25 years or more, and have yet to encounter this seizing problem. But, several other regulars on this NG will agree with you based on their experiences with ham-handed construction crews. Use the torque specs correctly, and you can stay out of trouble.

The reason I said element length was fairly redundant on all bands was the most important part to decent performance is efficient matching to the line. Sure, a half size dipole has slightly less gain than a full size, but not enough to really be noticed as long as you can get power to it. But thats the real trick.
Easier said than done to truly compete with a full size antenna. MK

Another consideration is all the possible mixing products that can occur at altitude that could include those caused by the plane's transmitters, and even signals from the ground (possibly a great many) that are quite strong due to line-of-sight propagation that could cause spurious mixing products, even to several orders. The more signals that mix together the more the likelihood of a product that could interfere, threatening the plane's safety. The possibilities for interference to avionics actually seem pretty high when you consider all the possible sources..

But it hasn't always been forbidden. In 1972 I worked Bill Leonard, W2SKE, on 2 meters FM while he was a passenger on a commercial airliner at 33,000 feet flying from Dallas TX to New York. (I was in southern Missouri) He was using the same type rig that I was - a Drake TR22 transceiver- running 1 - 1/2 watts which he said he was holding up to the window. The TR22 was a battery powered "handheld" but certainly not a handi-talkie, there were no HT's common in ham radio at that time. It wasn't until some time later that the ban came about.

Thinking back, I did some rather amazing things with my little 1-1/2 watt TR22. Like working repeaters 200 miles away full quieting when I hooked it to a VHF commercial hi-band antenna 200 feet up a tower. Several of us hams who were also motorcycle riders used them for motorcycle mobile.

Richard Clark wrote:
"Where is the 9W coming from (if all the reflected power is consumed in an isolator)?

The source of all incident power is the transmitter and that power is all newly supplied, not recycled, when an isolator prevents a recycle.

A mismatch between coax and load is between two immutable impedances which enforce separate voltage to current ratios. An incident wave hitting a mismatch has either too much voltage or too much current to be completely absorbed by a mismatched impedance which is either too low or too high to accept all the power beibg carried in the coax. The surplus must be rejected. Rejection means "Return to Sender".

The cause of the reflection is the discontinuity.

In the example, 100 watts must be delivered by the transmitter right now, if 10 watts is to be reflected, because the added isolator eliminates a recycled 10 watts to merge with 90 watts of newly emerging energy for an incident total of 100 watts.

If only 90 watts is available from the transmitter, only 9 watts will be reflected. 10% of the incident power is reflected, as I understand the problem. That isolator isn`t "green" because it is an enemy of recycling.

CAM, W5DXP wrote:
"The first derivative of DC is zero. The first derivative of an AC sine wave of any frequency is a cosine wave of the same frequency."

That makes sense as the derivative is the rate of change at a point. DC doesn`t change with respect to time. So zero is an appropriate first derivative A sine wave has maximum slope when its value is zero and zero slope when its value is maximum. A cosine wave can be characterized by shifting a sinewave 90-degrees and thus illustrates the slope of the sinewave at any corresponding point.

Cecil,
I sent a posting immediately after I answered your posting.
With respect to your drawing you are correct but please ensure that
it is the dipole that is driven. Also in my case the loop and
the dipole theyare coupled so that one side of the loop is in physical
and electrical contact. To determine the basics of the antenna you
should
review the use of such a circuit in a quenched spark gap transmitter
and how such a coupling is utilised plus 'energy distribution' curves
of same. Occillation knoweledge comes in handy but not necessary.
Yes it is really very old stuff that most have forgotten

The posting that I made afterwards apparently did not get out so I
will
repeat the basics now.
I have given up on the described antenna and this thread. I thank all
for their kindness and considerations and the extra leeway they have
given me in the past and these thanks also go to Mr Clark who I have
maligned in the past.
I wish you ALL a merry Xmas with your families and also a safe one for

> . . .

"We" is presumably the group of people running so much power that a few dB reduction of signal is of no consequence, but there's a danger of melting traps. That group would presumably be interested only in temperature rise.

As for the rest of us, though, the drop in field strength caused by loss is more important. For a given amount of loss, a large number of factors can influence temperature rise -- surface area, thermal conductivity of connected wires, how breezy it is, and the heat capacity of the trap, to name a few. The amount of temperature rise caused if the trap were to lose the entire power applied to the antenna is only twice the temperature rise caused by a 3 dB trap loss. A small breeze or poor thermometer contact could easily cause this much variation unless you're dumping in enough power to get the trap really hot. So with a field measurement of temperature rise, you might easily be unable to tell the difference between 2 dB and 20 dB loss.

So I'll exclude myself from the "we" group. I'm interested in signal strength reduction, and not how warm the trap gets.

Of course, if the coax between the transmitter and wattmeter is short,
that's what's known as same-cycle reflection. The reflection model
still works perfectly, i.e. it is mathematically consistent.

The total forward voltage increases because of constructive interference
mirrored by the destructive interference of reflected waves in the rearward
direction. That's re-reflected power.

> In the rearward direction, the

The total rearward voltage decreases with increasing destructive interference
between reflected waves. Every increase in destructive interference is mirrored
by a corresponding increase in constructive interference in the forward direction.
In a matched system, reflected power is involved in the destructive interference.
That makes the constructive interference in the forward direction re-reflected
power.

Use non-toxic levels of salt and you will get better soil conductivity and the grass won't grow faster. In clay soils the salt will stay put in sandy soils it will leach out.

If you want to build antennas it will be some of the best money you spend. Get a late edition with software. New is not necessary. The next thing you need is at least the demo version of EZNEC http://www.eznec.com/index.shtml to model antennas to see what height above ground, out of plumb verticals and such do to the radiation pattern and model most of the other design factors that go into an antenna.

I'm about to buy a shortwave antenna for my HF set and I'm thinking about a Diamond WD330S because I don't have much space around the house to use something else. I wonder however if this antenna works well on all the WARC bands. Who has tried such an antenna and in what way should it be used, as an Inverted-V, a Sloper, or as a Flat top antenna?

4413. Re: where do you connect a cable on an old Yagi antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-10 10:20:31 UTC
From: richie_r1ch@hotmail.com
Message-ID: <6ec14ee2.0212100220.6d1739cc@posting.google.com>
Source record: 129452

Here's a little diagram I typed up of what my antenna looks like. I'm new to this so I dont know what most parts of antenna's are called so bare with me on this.

```
1. ---------------|X|-----------------
|X|
2. -----------|X|-----------
3. -----|X|-----
|X|
4. -----|X|-----
| |
5. ---| |---
6. ---| |---
7. ---|_|---
```

The "| |" is the frame where all the elements are sitting on. The "X's" are 2 aluminum rods kinda like a coathanger that go in X patterns and it connects elements #'s 1,2, and 4. The third element is attached to the bottom of the frame while the others are all on the top. I have noticed that on the fourth element where the two rods are connected to, on the bottom of the frame there are two screws that look something like knobs, so you could take them off without a scredriver, Im thinking this could probably be a possible connection place. Also, in the middle on the side of the frame there are two nuts, but I think these are meant to screw on the pole.

Right now I'm running two 75ohm cables from the antenna. One to my TV and the other to my TV card on my PC. I havent bought the transformers yet, I just stripped the wires and have been connecting them to different spots. Is there a noticeable signal loss by just stripping the cable and just wrapping the wires around an element rather than using a transformer? I've connected just the middle part of the wire to the 7th element and could get better reception on UHF channels than I can when I connect both wires "one to each rod that forms the X pattern". But VHF reception is better this way.

where would you recommend the best connection place to be based on the little diagram?

How would I go about cleaning the antenna? Cause it's very filthy, It's dark gray already and from scrubbing it I can tell that I should be getting better reception cause the difference is big. I wanted to take it apart and clean each element individually but there are not held together by the usual screws. They are connected to the frame by something that looks like thumb tacks and and then a little circle with a border at the bottom. How do I take these off?

I'm already getting great reception on all my local channels but I want to get much better reception from the stations in San Diego. I'm in the Southern part of the Los Angeles county about 100 miles away. Sometimes I can get some of them with a little snow but watchable. And last night I was actually recieving stations from what I believe were coming from Northern Mexico. Because they are not listed in any of the sorrounding counties. And I can also get a channel 3 also in Spanish but very poor reception. I thought this channel was reserved for other purposes here? The reception on all these got far worse in the morning.

I'm hoping I can get better reception on these channels with the proper connection and some cleaning. From my roof I don't see any big buildings or trees blocking my view so I think I could do better.

thanks for replying

Not according to modeling. A 2m 1/4 wave GP with sloping radials at 40 ft vs a 1/2 wave at 40 ft is about .3 db difference with the 1/2 wave having the slight edge. But this assumes good decoupling. Many 1/2 waves fall short in this regard, and the edge could easily go to the GP in many cases. MK

But the Bird won't be as accurate as the factory-set power metering in the tx, regardless of the final load Z. That is the reason why the two meters don't read the same into the customer's load, not because the load has changed from the reference load in the factory.

The Bird also would not match the tx metering if the Bird was in place during final test and cal of the tx into that optimized load at the factory.

R. Fry

4th Edition (1955) was the last edition. The title was changed to
Electronics and Radio Engineering from the earlier "Radio
Engineering."

It was a widely used text and reference and can be found without too
much trouble in a good used bookstore. I see that I paid $7.50 for the
copy that I have, including the dust jacket.

Terman's Radio Engineering Handbook is also worth adding the library.

RE: Post below

A very good directional coupler, correctly adjusted, can have upwards of 60dB directivity. If it is designed to correctly sample both the electric and magnetic fields in the transmission line on which it is mounted, its output sample will not change with the location of the coupler along the line, for a given forward power in the line.

Using such a coupler on a transmission line conducting X watts of power into a perfectly matched load Z will show a 60dB difference in output voltage when looking at the forward and reflected energy (by rotating the coupler 180 degrees and refitting it to the line).

Now remove the termination from the line. The coupler shows the same level of forward signal as it did before, but the reflected sample is equal to it. I have confirmed this for myself while doing RF pulse measurements of TV broadcast antennas.

Now, if reflected power is imaginary -- how is this reality explained?

Crazy George wrote:
"Use the torque specs correctly, and you can stay out of trouble."

As usual, George is right.

Had a contractor erecting a tower in Minnesota. Bolt heads were showering upon the ground around the tower. The bolt boxes said "Made in Venezuela". So, I rented torque wrenches for the tower crew and after 40 years the tower still stands.

I would not characterize the Venezuelan bolt problem as a myth. Neither would I characterize stainless steel hardware siezures a myth. Like the Venezuelan bolts, if not over-tightened, this is useable, but still problematic. I`ve chiseled stainless apart to show how it`s done.

:-) Sloping radials not allowed when comparing a 1/4WL vertical with
a 1/2WL vertical because sloping radials make it longer than 1/4WL.
If you slope the radials enough, you have a 1/2WL vertical. To get a
valid comparison between a 1/4WL vertical and a 1/2WL vertical,
the ground plane must be horizontal.

>
>

Define what you need better. If you go to a yagi, it will be directional.
Since these devices are used in vehicles, are you leaving it to us to
assume that a directional antenna aimed perpendicular to the road
will do the job to monitor passing vehicles, or do you need a full 360
degree
circular coverage area?

If you need a directional antenna, get a hold of a Tessco catalog, and look
for a good fiberglas panel antenna, or radome enclosed short yagi.
Railroads use flat panels for reading car tags on passing cars.

Peter

Sorry Andy!

The microwave oven is tested for emissions, and by the way YOU wouldn't want
a microwave that had any serious leakage right?

The on board satellite phones again have been rigorously tested for use in
the aircraft.

So we shut down the laptops, cell phones, and other toys at critical times.

I'm in full agreement on the rules, as I notice the pilots these days have
too much
dependence on the nav. toys, and too little common sense.

Stupid bureaucratic rules are more like: I'm shining my light in your
window and your
not allowed to look at it. (We can't listen to cell phones!)

Richard Fry wrote:
"Now, if reflected power is imaginary-- how is reality explained?"

Yes. And why would a trough/slotted line demonstrate standing waves?

Some people seem to delight in proclaiming "faults" of the Bird wattmeter when it is hailed as the standard among field instruments. The Bird shows reflected power and satisfies most of its users.

If there is NOTHING OBSERVABLE that can distinguish between my model
and Steve's model and assuming there is nothing wrong with either
model, my model shows that all the reflected power is 100% re-reflected.

How then, can Steve assert the following as absolute truth? "A total re-
reflection of the re-reflected voltage, current, and power does not
occur at the match point." Don't you think he should have prefaced that
statement with, "The particular model that I am using indicates that a
total re-reflection of the re-reflected voltage, current, and power does
not occur at the match point. Other valid models may indicate the
opposite result."?

"---not because the load has changed from the reference load in the factory"

If the wattmeter is to be inserted and removed at higher VHF, better accuracy is obtained by making the Bird part of a 1/2-wave coax jumper. The length of the Bird body may otherwise affect readings and performance, if the load is mismatched.

Actually, it does have rhyme and reason. Current cell technology
would be swamped over a wide area by a few cell users in airplanes.
The MOST IMPORTANT reason is that the use of cell phones would
interefere with the revenue stream from the "Flite-Fones".

|during final test and cal of the tx into that optimized load at the factory.

Okay, I'm not just trying to be argumentative, I don't sell Bird watt meters for a living, nor do I believe they are anything more than a rugged field instrument but...

I don't know what scheme you had for power monitoring so I cannot comment on its accuracy in the fact of varying load Z, but just because the Bird spec is 5% of full-scale doesn't necessarily mean that it is 5% in error. It could be right on.

What you had was a correlation problem between vendor and customer. Believe me, I understand those. When I was the responsible engineer for the Phoenix missile transmitter, which used 16 matched Impatt diodes in the final stage, we wound up building and calibrating several "identical" waveguide test fixtures used to characterized the diodes. We sent one to each of our diode suppliers and required that each diode be characterized in the supplied fixture. We also specified the other test equipment and supplied the software to control it. Only then did we remove the correlation problem.

Calibration of the fixtures was non-trivial too since the oscillator was constructed of 1/4 height X-band waveguide which required some effort to calibrate and in those days, the company Metrology lab was a 400-mile plane ride away.

Well that depends on which type of wolf spider it is.
The breakdown voltage on a red wolf spider is very
high, as it is with the gray wolf spider. Now if it happens
to be a werewolf spider then you have some serious
problems because they won't die unless shot with a
tiny silver bullet! ;^)

Hi OM,

From your diagram it appears you have two interleaved antennas, one for UHF (without X connections) and one for VHF (the x connections) and that the UHF couples into the VHF for getting signal back to your TV. It may also be high/low band VHF (for channels up to 13).

> on the bottom of the frame there are two screws that
>look something like knobs

Connect the transformer there.

If the higher frequency antenna does not couple into the other, larger one, then there should be a corresponding pair of bolts located on element 5 for a second, higher band connection (needs transformer too).

Don't go there, antennas work fine as long as the
dirt/film/what-have-you does not hang like spanghum moss.

Hi OM,

Sounds like you are at the limit of your antenna's gain if you have
made the proper connections. The real key to success is height after
that.

So If you have a wall outlet in your home with nothing plugged into it
(open circuit) does that mean that there is power flowing to the open
outlet and then being reflected back into the line?

Assuming you are high level modulating the output stage, you pick the turns ratio of the transformer so that the Peak audio voltage is equal to the DC supply voltage of the RF amplifier. So, if the RF stage runs at 12 VDC, and the audio amp puts out 12 V p-p, you need a 2:1 voltage step up for 100% modulation. Except for very low power, Couple of things to watch for: For this example the RF transistor would have to be rated for 24 VDC. You probably can not 100% collector modulate a transistor amp. You might have to apply modulation to both the output stage and the driver. You might be able to use modem telephone coupling transformer, the kind that has a DC current rating (usually about 100 ma)

Gary Schafer wrote:
"What I was referring to was "peak envelope power" which is 4 times the carrier power with 100% modulation."

Looks like that to me too. There have been some really funny numbers posted.

RMS volts times RMS amps = Average Power
Sq, rt. of 2 (rms volts) = Peak Volts
Sq. rt. of 2 (rms amps) = Peak Amps
Thus: 2 (rms volts x rms amps) = Peak Power

Peak Envelope Power is different. For 100% AM, the peak carrier is alternately doubled and reduced to zero. Doubling the voltage also doubles the amps. Thus the carrier multiplier is 4 times the average carrier power to produce peak envelope power.

Best regards, Richard Harrison, KB5WZI

"So, if the RF stage runs at 12 VDC, and the audio amp puts out 12Vp-p, you need a 2:1 voltage step up for 100% modulation."

Agree you ned 12 volts peak to double the carrier volts, and -12 volts to reduce the carrier to zero. However, a push-pull transformer will have nearly 24 volts peak to peak on its primary at maximum output using 12 volts on the collectors.

The collector to collector impedance of its load is:
Rc-c = 2Ec/Po

The collectors are switched from Ec to zero alternately on each 1/2 of the cycle and in push-pull, these 1/2-cycles are phased to aid. We have a 12V peak positive alternation and a 12V peak negative alternation. Added together, this is 24V peak to peak.

Best regards, Richard Harrison, KB5WZI

I was mistaken about mentioning a Yagi; I just found out that these
are directional.

It looks like a co-linear would be best for my application. Know of
any good suppliers (preferably online)?

I still don't think the difference would amount to more than a half db
, even with flat radials. In the real world, I never use flat radials.
The sloping radials give a better impedance match, and like you say a
very small amount of gain. But the increase in gain is likely
unnoticeable on the air. MK

He could use a Jfet (no?) and be able to get a larger voltage swing. But, his project is very low power, so what matters peak voltage swing? He could also modulate the emitter thru another transistor (MOS, JEFT or bipolar), or series modulate the collector voltage in a similar manner.

how do I connect it there? There are no screws there. And it is just a single element. Do I just peel the ends off of the transformer and tape them there? Do I connect both ends since #4 is only a single element.

thanks again

It is unfortunate that the cell phone calls made by the victims of
9-11 from the planes didn't cause some useful interference.

How the does this guy stay in business. Most guns stores I visited only have
about 300 guns

The problem in the Pacific NW was the guy was a Black Male and the cops
would not screw with him because they
are afraid of another Rodney King incident. I have been a cop and know what
is being told to the troops.
A Chief of Police does not and I REPEAT does not allow their people to screw
with minorities
for that particular reason.

While on the DC sniper (I served my time in law enforcement in the DC metro
area) noticed
how after they DID NOT get their PROFILED WHITE MALE 30 to 40 YEARS OLD,
This entire
story was flushed down the media toilet after it was learned they had
captured an Islamic Black Male and
his juvenile side kick from the Caribbean. This is will all be settled
quietly with the jerk wad getting
life somewhere and his ties to the Nation of Islam and their anti-Christen /
Jewish / anyone else who
does not agree with them BS will swept under the carpet.

The real issue is not Israel, UK, US or any other country, this issue Islam
is using our values against us
with the Liberal, peace hoping flower Childs of my generation helping them
along. Their goal is
total world domination, they are the Nazis of the 21st century. They hate
you, me and anyone else
who is different from them and not of their pure religious beliefs they hold
near and dear to their
AK-47s. Instead of chanting Heil Hitler they chant Praise Allah as they
prepare to kill, just listen
to the video tapes of the people involved.

>

> death to terrorists!
> Richard Clark, KB7QHC

No argument here, in fact the large number of people owning guns in this country I would bet has minimized
their attacks.

Finally I salute the woman in Georgia who reported what she heard. No will one know if she stoppped
a potential attack. The Islamic soldiers are taught to lie when caught and many of us did not believe
their BS for one minute.

Since the voltage changes from from +160V to -160V and back 60
times per second, there *is* current flowing in the wires. I
assume that if you had a 3106 mile long low impedance transmission
line, you would get one wavelength of standing waves.

It seems simple enough to design/build one with switching diodes
controlled by the LPT1 port. Have you checked TenTec to see if they
have such an offering for their radios? I understand there are some
Yahoo user groups for the WinRadio and TenTecs,,,maybe somebody there
has a better suggestion

Whatever gets you through the night, Andy. There is a big difference between the *controlled* RF environment in the aircraft (i.e. all the aircraft RF producing equipment that has been tested, shielded and verified) and the *uncontrolled* RF environment (i.e. dozens of cellphones transmitting at once, dozens of pagers, two-way radios, etc.).

I, for one, would much rather have every passenger turn off the damn phone than having so much as a 1% increased risk of crashing.

About ten years ago, I witnessed a funny thing when one of the co-workers whipped out his cellphone and started jabbering - I had a board on my test bench and as he was speaking about 5-6 feet away, one of the 1N4148 diodes on the board literally lit up and burned. The board was not even powered up at the time, btw.

There is a good reason most of the hospitals don't allow cells in the building or at least in the vicinity of the intensive care units. Or is that just another bureaucratic conspiracy?

Hi,

I am interesting in mobile antenna for my rabbit (golf) car.
Could someone explain me what is (are) the difference between the
antennas sold by Hi-Q vs e.g. Hamstick ?
The first company sales antennas 10 times more expensive than the
second one ... For me both products are similar even if the first
looks more robust, but the first are rate at $300, the second $30 or
so... That makes a first big difference. Are there others, technically
speaking ?

Thanks
Thierry

Of course, I was referring to the proverbial "standard" S-unit. :-)
The other night, when I switched from 100W to 400W, the ham I was
QSOing with said, "Wow, you jumped 20 dB!" Who needs a kilowatt? :-)

Like so many things it depends on what level of performance you are seeking.
The hamstick positively stinks on any frequency below 20 Meters. And if you
are going to operate on all bands,
your best bet is the screwdriver. After all, by the time you buy enough
'sticks to cover 8 bands, you will have spent as much for less performance.
Then you'd have to consider where you'd store
all those sticks in a VW.

Yeah, I was going to suggest that too. Audio modulate the voltage regulator
that feeds the output stage, then no transformer. Set the quiscent value of
the DC out to 1/2 the normal value. Even simpler might be to feed the DC to
the output stage through an emitter follower that has its base biased at 6
or 7 volts, with 10 V p-p audio capacitively coupled on top of that.

I read an article once a few years ago on this subject... The article discussed a test done by the FAA where they "fried" a plane with microwaves, and other stuff, with all the electronics on the plane active. While one of us would have been cooked, the electronics continued to work fine. There are a couple of reasons why they don't want phones used on the planes. First, it would take away from the income generated by the flight-fones. Secondly, as this was also tested, if you were to use your phone on the plane, while the hardware from the providers would be able to keep up with you, switching from cell to cell, etc., the software would not be able to keep up with you and their billing would be hosed.

No flames please.. Just repeating what I read...

DJ,
I'd say pick the one that makes the lea$t dent
in your back pocket. There really isn't any
advantaqe to an antenna with a big coil(s) over one
that has no coil(s). The coil doesn't give you any
advantage other than a shorter antenna. Won't handle
any more power, reach further, or any of the other
nonsense you hear about them. Also, if an antenna
works well with high power, why would it ~not~ work
well with low power? It's your money so you spend
it how ever you want to, but I certainly wouldn't
waste mine on any of the antennas you listed.
'Doc

4473. SWR Bridge component values-Henry 2K4

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-11 03:02:21 UTC
From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3df6b0dc_2@news1.prserv.net>
Source record: 129412
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,sci.electronics.repair

The used 2K4 I bought suffered some kind of disaster inside the little aluminum box containing the bridge. Someone probably tried to put a kilowatt into an open circuit. The inside of the box is blackened, and spotted with fine particles of molten metal. As a repair, some previous owner simply removed most of what was in there, leaving the toroid around the center conductor, and the two .01 caps on the RCA jacks. I have a corrected copy of the schematic, and would like to obtain a few pieces of additional data before I tackle rebuilding it.

The drawing (SWR Bridge, December 1970, By: WCK) shows a unterminated winding (L80) grounded on one end, and apparently wrapped around the center conductor. There was a short piece of magnet wire still stuck inside the insulator in the center of the toroid, and I suspect this must have been a simple Faraday shield. How many turns, and what spacing was it? And, how many turns in the main coupling winding around the toroid (L81)? I count 64 remaining on this one, which may be close to the original number.

Second, some component values. The trimmers (C80 & 87) connected to the center conductor were probably in the range of 7 pf. Is that correct?

Are the RF chokes (incorrectly shown as C82 & 84) 0.5 or 1 mH, or something else?

The SWR bridge shown in many ARRL Antenna Handbooks looks very similar to what is shown on the Henry schematic, so I am using it for some guidance. Has anyone else compared the two?

All constructive comments appreciated, and yes, Reg, I know measuring SWR doesn't tell you much. I just want it for a relative output indicator.

I'm in the process of retiring (modest budget) and hoping to do some HF and VLF antenna work. I have a Palomar R-X noise bridge that has served me reasonably well but it doesn't go below 1 mHz. I've used a borrowed MFJ 259 and Autek RF-1 but not enough experience to make a decision other than they sure are convenient. I've reviewed the Dec. 87 QST article on a Lab-Style RX noise bridge as well as the Aug. 89 QST on Improving R-X noise bridges by using a binocular ferrite core for the transformer, the "heart" of the noise bridge. I'm looking for intelligent opinions on what I should consider for my last or next to last antenna bridge. Right now I'm sort of leaning to building the Lab-Style in Dec 87 QST substituting the binocular ferrite core but I'm not sure what it'll take to get the instrument down to VLF and maybe LF, maybe two instruments or a band switch.. Have there been any articles elsewhere that I should find and read? Are there commercial instruments perhaps by HP or others that might be on the used market and should be considered?

Sorry I mean't #4, missread your diagram, put the leads from the matching
x-former on them screw terms,put a F conn on the end of your coax and screw it
into the x-former. you can use a splitter
on the house end to split between your tv and tv card.Be aware that the
splitter will impart some signal loss. Also note that the antenna you describe
is not a very high gain unit,so dont expect any miricles

Just use a decently sized audio IC to directly drive the PA stage collector.
For maximum modulation depth, the driver stage should have some audio
applied to the collector as well.

Sorry for the delay -- I've been really busy and wanted to read this carefully before responding.

The following comments assume sinusoidal steady state conditions.

I don't disagree with any of the examples Steve presented here. However, I also didn't get a clear idea of "what happens to the reflected power" from the analysis. To me, forward and reverse (or as some like to say, reflected) power are average (D.C.) quantities calculated from forward and reflected voltage and current waves. The actual instantaneous power at any point along the line is a combination of a D.C. term and a sine wave at twice the frequency of V and I. While well known principles can be rigorously applied to the analysis of traveling voltage and current waves (as Steve has done), I have yet to see equations or even definitions describing such things as reflection coefficient for a reflected power wave. Forward and reverse power are useful concepts for some purposes, but more care should be used in assigning attributes to them that they don't have.

I'd like to present the following hypotheses for comment. All are restricted to single frequency steady state conditions and time-invariant components. (That is, component values can't change with time.)

For the first one, I'll define a "source circuit" as either a voltage source with series resistance or current source with a shunt resistance. For this circuit:

1. The power dissipation in the source resistance can be predicted completely with no other knowledge than the voltage of the voltage source or current of the current source, the value of the source resistance, and the impedance seen by the source circuit.

Comment: A given impedance as seen by the source circuit can be made from any number of combinations of transmission line and load, with very widely varying calculated values of forward and reverse power. But as long as each presents the same impedance to the source circuit, all will result in exactly the same amount of source dissipation.

For the second hypothesis, I'll relieve all restrictions on the source circuit, and allow it to be any kind of circuit, linear or nonlinear, including a transmitter. You can even include an isolator within the source circuit or among the external components if you'd like:

2. If any combination of transmission line and load (or any other combination of linear components) is connected to the source circuit, resulting in an impedance Z1 seen by the source circuit (with Z1 being

V/I at the source circuit output), then any other combination of transmission line and load (or any other combination of linear components) presenting the same impedance Z1 can be connected to the source circuit and will result in the same dissipation within the source circuit. And, for that matter, in the same power delivered by the source circuit to the external components. Connected transmission lines can have any amount of reverse power, as long as the impedance seen by the source circuit is Z1.

Comment: Even for this much less restrictive condition, the source dissipation is uniquely determined by the impedance seen by the source circuit.

3. No single-frequency steady state source circuit can distinguish between a simple lumped component load and a load connected to a transmission line having any amount of forward or reverse power, as long as both present the same impedance to the source circuit.

Does anyone disagree with any of these hypotheses? If so, please present a numerical example showing it to be false.

If you accept these hypotheses, there's a strict one-to-one correspondence between the impedance seen by the source circuit and the source circuit's dissipation (and delivered power), but there's no such correspondence between the reverse power on a connected transmission line and the source circuit's dissipation. (I'll give a nod to Wes' observation that there is such a correspondence if you restrict the transmission line impedance to the single value that an isolator is designed for, and include the isolator in the source circuit. This combination has a dissipation that is directly proportional to the reflected power because of the way the isolator disspation varies with load impedance. However, hypothesis 2 still applies to this source circuit.)

Thanks for the clarification. I agree:

If you connect a source having an isolator at the output to a transmission line whose impedance is equal to the isolator's impedance, the dissipation of the isolator's resistor is equal to the reverse power on the line.

Of course, you can substitute a lumped network with no forward or reverse power for the transmission line/load and get the same dissipation, as long as the Z looking into the lumped combination equals the Z looking into the line. Or you can connect lines of different impedances and different reverse powers and get the same dissipation as long as the Z is the same looking into the line.

But it's not enough just to have a good source match -- a voltage source/series resistor or current source/shunt resistor can have just as good of a source match as the isolator, but it doesn't have this same relationship between reverse power and source dissipation that the isolator does. The HF generators I've seen fit this model pretty well.

RE: Below

True for the Bird (and similar) metering systems, and this is another reason to trust the tx metering. Most newer transmitters use an electromagnetic directional coupler, whose output voltage is not affected by its location along the line regardless of the load match.

RE: Earlier post below...

If reflections are imaginary -- how is the following reality explained?

A very good directional coupler, correctly adjusted, can have upwards of 60dB directivity. If it is designed to correctly sample both the electric and magnetic fields in the transmission line on which it is mounted, its output sample will not change with the location of the coupler along the line regardless of load SWR, for a given source power in the line.

Using such a coupler on a transmission line conducting X watts of power into a perfectly matched load Z will show ~ 60dB difference in output voltage when looking at the forward and reflected energy (by rotating the coupler 180 degrees and refitting it to the line).

Remove the termination from the line. The reflected sample now equals the forward sample, less line loss to the load and back. I have confirmed this for myself while doing RF pulse measurements of TV broadcast transmitting antenna systems.

Roy Lewallen wrote:
> Does anyone disagree with any of these hypotheses?

They sound good to me, Roy. And I would add, if the same results
are not obtained using the reflection model, then the user of
the reflection model does not fully understand the reflection
model and has made one or more errors when trying to use it.
In particular, one cannot analyze the system half-way using
the reflection model and then switch in mid-analysis to the
circuit model. One way to avoid that pitfall is to install
a piece of transmission line between a source point and a
virtual impedance. The Z0 of that transmission line must be
such that the SWR is 1:1 yielding a Z0-match point that can
be analyzed using the reflection model as I have presented
it in my rebuttal to Dr. Best's QEX article. Once the reflections
are eliminated by a Z0-match, the analysis becomes much less
difficult. And installing a piece of transmission line with an
SWR of 1:1 (no reflections) doesn't change anything except the
phase of the forward wave which is the initial reference point
anyway and therefore doesn't matter in the analysis.

It must be understood that in the steady state, the power carried by a wave and the power dissipated in a load are the net result of a continuing process of multiple wave reflections and re-reflections within system. The level of voltage and current (and therefore power) reflection and re-reflection at either end of the line are a direct function of the terminating impedance (reflection coefficient) at the end of the line.

In the line itself, understanding "what happens to power?" (in the steady state) is an easy question. The total forward power is determined from the total forward voltage and current. The total rearward (reflected) power is determined from the total rearward voltage and current. The net power delivered to the line is simply equal to the total forward power minus the total rearward power (after making some assumptions about Zo).

Understanding "what happens to reflected power at the source?" (in the steady state) is not an easy question and cannot be answered by looking at the total forward and rearward power *in the line*. An analysis of steady state power *in the line* does not provide a valid understanding of the relationships between source power, reflected power, re-reflected power and total forward power. The analysis must be performed using voltage and current and it must be recognized that net power is simply determined from the voltage and current interactions within the system.

Let's consider this further with a very simple example below:

>

Absolutely correct, with the understanding that the steady state impedance
seen by the source is a direct function of the reflected wave(s) created by
the load at the end of the line. Without these reflections, the source
would only see an impedance equal to the Zo of the line.

Correct. From the source or transmitter's perspective, it is only the
steady state Z, seen at the transmitter output that matters.

There may not be a "one-to-one" relationship between the reflected (rearward) power and the source power dissipation but there is a "one-to-one" relationship between the rearward voltage and current and the source power dissipation. In recognizing that the reflected voltage and current play a direct part in determining the Z seen by the source, they must play a part in determining the source power dissipation.

Lets look at the simple example.

Here's the TL circuit:

100 V -- Zs = 25 ohms -- 1 WL 50 ohm line -- 25 ohm load

Using simple transmission line theory we can remove the line and draw the equivalent circuit:

100 V -- Zs = 25 ohms -- 25 ohm load

Steady state conditions:

The voltage across each 25 ohm load is 50 V. The total (steady state) power dissipation in each of the 25 ohm loads is 100 W. Total power dissipation in the system (in the steady state) is equal to 200 W.

Steady state condition in the line:

Pforward = 112.5 W; Prearward = 12.5 w; Pdelivered to the line (load) = 100 W.

Now let's look at how the 12.5 W of reflected (rearward) power affects the source and steady state conditions:

To understand the effects of reflected voltage and current (power), we must first look at what happens when the source is first energized. When first energized, the source sees a transmission line with an impedance equal to 50 ohms. The INITIAL forward voltage in the source impedance is equal to +33.33 V and the INITIAL forward voltage in the line is +66.66 V. The INITIAL forward power in the source impedance is 44.44 W and the INITIAL forward power in the line is 88.89 W. The total power dissipation in the initial state is 133.33 W. If the line were infinitely long or terminated in a 50 ohm load (no reflections) these INITIAL conditions would not change. This is an important point for all the people that believe reflected power (reflected voltage and current) is not "real".

Lets see how the reflected wave(s) create the steady state conditions. As the system transitions from the initial to the steady state, there is a process of reflection and re-reflection within the line between the source and the load. To analyze the effect of this process, let's jump to the steady state and consider the 12.5 W of steady state reflected power and how it affects the INITIAL conditions. (We could analyze the effect of each individual reflection but this would take too long)

The 12.5 W of rearward power is associated with a rearward voltage equal to -25V. At the source, this rearward voltage (wave) sees a terminating impedance of 25 ohms and a reflection coefficient equal to -.3333. The total re-reflected voltage is equal to +8.33 V and the total reflected power is equal to 1.39 W. Note that the total forward voltage is equal to the vector sum of the INITIAL forward voltage and the re-reflected voltage. The total steady state forward voltage is equal to 66.66 V + 8.33 V = 75 V and the total steady state forward power becomes 112.5 W (75^2/50) (vector voltage superposition at work).

At the source, the total rearward voltage created by the rearward wave is equal to the vector sum of the incident rearward voltage (-25 V) plus the re-reflected voltage (+8.33 V). The total rearward voltage delivered to the source is equal -16.67 V. The total voltage developed across the source impedance is equal to the INITIAL forward voltage (+33.33 V) minus (note the + reference direction) the rearward voltage (-16.67 V). The total voltage in the source impedance is equal to +33.33 V - (-16.67V) = 50 V. The total source power dissipation is equal to 100 W (50^2/25).

Several important points to note:

1. The level of voltage, current (and power) reflection or re-reflection are determined by the reflection coefficient as determined at the end of the line. This is consistent with general transmission line theory.

2. All of the forward and rearward voltage, current and power levels are determined through vector superposition of voltage and current. Power is a resulting scalar quantity. This is consistent with general circuit theory and superposition.

3. Reflected (rearward) voltage and current directly determine the steady state conditions within the source and line. The reflected wave (V and I) directly determine the total Z seen by the source (the reflected wave is very real).

4. In this example, the power dissipation within the source, the transmission line and in the load increase relative to the INITIAL conditions as a direct result of the reflection and re-reflection process. This does not violate the law of conservation of power.

5. The total forward power increases as a direct result of the vector superposition of forward voltage and current. This DOES NOT require a corresponding destructive interference process (reduction of power elsewhere) to balance the law of conservation of power (The power dissipation in the source increases at the same time the forward power increases - it does not need to correspondingly decrease). Voltage and

current superimpose in both directions - power is a resulting scalar quantity. The law of conservation of power is satisfied in that the total power delivered to the system is dissipated within the system.

With that, I wish you all a Merry Christmas and Happy Holidays. I'll be off for awhile (unless the impending fractal optimization is posted)

Take care,

Steve VE9SRB

During the spring of 2003 I hope to go to Haiti and wish to take along the minimal amout of radio equiptment so is they a simple wire antenna that can work several bands without a tuner? The bands I hope to work are 75, 20, 17, and maybe 15 meters. I may bring a tunner but the lest amount of stuff I have to take along the happier I'll be.

4489. Stub-line Transformers. New program.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-11 15:56:48 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <at7n80rjd1@sparta.btinternet.com>
Source record: 129328

NOW AVAILABLE

New Program " STUBTUNE.exe "

This program assists with the design of stub-line transformers used for such purposes as matching the feedpoint impedance of balanced radio antennas to the Zo impedance of the transmission line from the transmitter. This program is applicable only to balanced-pair lines. Transmission efficiency theough the transformer is calculated.

It is an improved version of program STUMATCH.exe in that it takes into account conductor loss in the transformer and is therefore more accurate when extreme ratios of (Antenna Impedance)/(Feedline Zo) are involved. Operating procedure is more complicated than STUMATCH. However it performs calculations beyond the facilities offered by the Smith Chart,

The program is peculiar in that the Zo of the feedline is not entered. All input data is variable in small up/down increments until the input impedance of the transformer is equal to the Zo of the line to be matched. Educational.

STUBTUNE is self-contained in one small file, download in a few seconds from website below, run immediately.

Rick,

Just take a hank of about 40 feet of thin, stranded, plastic-insulated, flexible wire to hang out of top-floor hotel windows or throw over trees.

Dont forget ground connection of 10 feet of wire terminated with a big aligator clip. Have two lengths. Great for connecting to hotel water pipes on opposite sides of the bedroom.

Take a few small home-made bottom-loading/tuning coils wound on cardboard tubes. Plus a 300pF variable capacitor. Make your own tuners as you go along. A few aligator clips and wander-plugs help. (On one of my trips I took a small soldering iron. Don't forget a little resin-core solder.)

Small screw driver (a knob may become loose). Small wire cutter/nipper/stripper (you will wish to change antenna length).

Egg insulator or small bits of plastic with two holes drilled in them.

Mike, phones, key, pencil and paper, log book.

Make a list of bits and pieces. You will be glad you did. But your list of essentials will not be complete until after your second trip.

Don't forget the rig.

Yup I checked ten tec and nothing is there about this stuff.
Winradio has a plan for one but I'm not an expert in electronics so I have
no idea how to put it together.
Perhaps I will need to make a simple manual switch.
Any idea what parts should I use to minimize the signal loss?

Why not take dipoles for the bands you want to use, or better yet a dipole for 75 and make up wire verticals for 20, 17, and 15? Verticals have much lower take off angle than dipoles. A 23 ft vertical and your tuner makes an excellent antenna for the DX bands.

You may want to reconsider 75. In the tropics, it is a very noisy (QRN) band with short range local contacts, if any, during the day. It opens up a bit in the middle of the night.

To answer your question, the rule for most antennas is "bigger, higher, better". Hang the longest, highest wire you can throw over two palm trees and hook the mid point up to your tuner with either coax or even better, open wire feed line.

Palm trees make great antenna supports.

To travel light, why not purchase wire and rope at a hardware store once you arrive in Haiti? However, I would bring your tuner and the feed line of your choice with you.

What do you use at home?

Good luck!

Just use an off-the-shelf rotary switch mounted in a metal box with
sockets. The loss will be negligible.

RE: Funny numbers

You are right. I hadn't used that spreadsheet in a long time, and apparently I had last saved a polluted version of it. Sorry about that.

Below is a run of the corrected version, done for the more typical 50-ohm load Z; also showing how the peak power rises with asymmetrical modulation. Negative peaks are held to 100% modulation, but positive peaks can go above 100%.

Such waveforms occur naturally in human speech, and can also be created/enhanced by audio processors (commonly done by AM broadcast stations).

Add some antenna system SWR as shown in the bottom group of numbers, and some transient voltage induced across the antenna by nearby lightning, and you can see why antenna and transmitter system components can have a tendency to arc.

Richard Fry

You have made some errors in your application of the wave model. Given the
following two examples, if you don't get the identical answer for both
systems, you have made the same error that you continue to make and refuse
to recognize. The error that you are making is switching from the reflection
model to the circuit model in mid-analysis. That's a well known no-no.

100V source-----50 ohm feedline---+---1/2WL 150 ohm feedline---50 ohm load
25 ohm source

100V source-----1/2WL 150 ohm feedline---50 ohm load
25 ohm source

Using the reflection model I get identical results. Do you?

Steve, you are still confused. If what you say is true, please show us
how to hook up two IC-706's each outputting 70.7V at 1.414A to obtain
a single wave of 141.4V at 2.828A. The conservation of energy principle
cannot be suspended just because you say it can. Every nanojoule of energy
is conserved. You still don't understand that destructive interference energy
in one direction causes an equal re-reflection of constructive interference
energy in the other direction. A transmission line must obey the same
conservation of energy principles as a transformer. Please show us how
to input two signals of 70.7V at 1.414A into a transformer and obtain
141.4V at 2.828A out of the transformer. If you cannot do it with a
transformer, you cannot do it with a transmission line without additional
energy from somewhere. That somewhere is re-reflected energy.

A transmission line is an energy pipe. If we have a matched system, we have energy input into the pipe at the source and no energy coming out of the source end. The only energy coming out of the system comes out of the load end. Therefore, any energy in the system that has ever been reflected back toward the load MUST SOMEHOW BE RE-FLECTED back toward the only energy output point that exists in the entire system, i.e. the load. We can argue over exactly what mechanism causes the re-reflection but there can be no doubt whatsoever that 100% re-reflection MUST SOMEHOW happen. Anything other than that simple concept is simply a hoax. After a year and a half, you still haven't answered this extremely simple multiple choice question:

In a matched system, the reflected energy:
1. flows into the source
2. stands still
3. disappears from the system
4. is re-flected back toward the load
5. Willy nilly obeys Dr. Best's every whim

Those are the only possibilities, Steve. Which one do you choose?
Why do you refuse to answer such a simple question?

It is funny that you mentin hospitals. My girlfriend is a nurse in the ICU of Baylor Medical in Grapevine, Texas. They have signs all over the floor (and every other floor for that matter) prohibiting the use of cell phones. Now, according to the chief resident the signs are there because of the noise, lack of consideration, and general disturbance the phones ringing and people using them cause. He didnt mention any other reasons. So dont speak about what you dont know....

Richard,

We went through this kind of thing here some time ago. If you want to see reflections, transmit narrow pulses at a rep rate that is much slower than the propagation delay of the cable. Now connect a 'scope someplace near the source, and you can seee the reflection coming back if the cable is not terminated in Z0. If the source impedance is not Z0 either, you can see the pulse bounce back and forth until it finally damps out. This is a common method by which cable testers work, because it will tell you the distance to any discontinuety.

First, I am not a radio expert in any shape or form, so please excuse the following question!

I need to transmit approx. 72 mW at a distance of about 18 inches (~1/2 m) and would
like to stay at frequencies that are below the Mhz range if possible.

I have tried looking up this type of info, but have been unable to find anything useful.

Thanks for any help antenna, circuits, info...

Aron

Source record: 129339

Hello!

Try a Conrad-Hertz-Windom antenna (FD4): 41.5 metres of isolated electric wire cut at 1/3-2/3, a 1/6 current balun, RG58cu or 300 Ohms tween lead depending if you want to have the balun placed right out of the shack or not and eventually an antenna tuner.
If you use the same sizes as the Fritzel FD4 2kW model you should work from 80 to 10 even on WARCs with slight tuning.

We have signs banning cell phones in our student computer rooms. Not because of the disturbance caused by ringing or by people talking on them. We ban them because they cause floppy disks to become corrupted in the disk drives. When the phones start transmitting to try and find their nearest cell (and if it is within 4 feet of the computer and the computer has a diskette inserted) there is a 75% probability of diskette corruption.

That's all really -- except if there's even the faintest chance I might get killed because a cell phone interupted the electronics of an aeroplane and caused it to crash or interfered with the medial equipment keeping me alive in ICU: I'd ban them there too!!

I'd rather live without a cell phone than die because of one -- even if the odds are minute.

> to take along the happier I'll be.

I run my 130 ft dipole on all those frequencies without a tuner.
I vary the length of the 450 ohm ladder-line to achieve a match.
On those bands, here are the ladder-line lengths necessary for
me to achieve a match:

3.8 MHz - 99 ft., 14.2 MHz - 105 ft., 18.14 MHz - 95 ft., 21.3 MHz - 88 ft.

Your antenna would not tune exactly the same as mine but you can tune it
before you leave on your trip. With a basic ladder-line length tuned to
21.3 MHz, I could have three extensions of 7 ft, 4 ft, and 6 ft which
I add to achieve a match. Banana plugs/sockets work great for these
extensions.

Hi Aron,

Use an 18" transmission line.

Any other answer demands to know how much power must be received. If
it is this same 72mW, you may already be in trouble insofar as
violating FCC power limits, antenna size and so on. Even for 18
inches.

Consider doing it optically where at this power level and frequency
you could easily transmit miles.

Hi,

This product is very simlilar to wellbrook's active magnetic loop
dia.1.1m) suited for listening purposes - ONLY - between 1.5-30 Mhz
(ALA1530) or 3-30 Mhz (ALA330) that provide quite good performance, an
IP2= +70dB, IP3= +40 dB with some senstivity to strong
intermodulation.

Note that if your RFI are quite strong (S9), the magnetic component
will not suppres them contrary to what state their ads. I tested both
products from Wellbrook, so i suspect this new brand to not work a
better way.

Review and comments on eham.net or

>

Hi,

OK I understand that I have to buy as many stick as band to work...
:-((
As you say in that case I prefer to buy a screwdrive like an Hi-Q.
Looks compact seems to be an excellent performer, even if a bit
expensive.

the other choice should be to install a R8000 on a tripod... but 10m
high to bend each time I worked in mobile is a tedious task...

One problem to solve, find a way to place the Hi-Q on my car roof top
with large magnets. Will see that with the manufacturer.

Thanks for the info

You have described the essence of the RF pulse tests I was doing. This tests permits evaluation and physical location of various discontinuities along the transmission line, and shows the antenna reflection at the far end of trace. The antenna match is adjusted to minimize the pulse return from the antenna, itself, with little affect from any VSWR produced by/in the line, itself. Very effective.

> to take along the happier I'll be.

Try a center fed wire antenna with flat top length of 79 feet
fed with 58 feet of 300 ohm twin lead. It will give close to
series resonances at 3.8, 14.1, 18.1 and 21.3MHz. Use wire of
number 22 to 14 for flat top; not critical. The impedance won't
be really high but you will still need a tuner. Forget the balun.
(remember to multiply the feedline length by velocity factor, ~.85)

See http://www.qsl.net/aa1ll/cfwire.htm for details on multiband
wires.

Modulating both the driver and PA is excellent. Using a Vreg to modulate Vcc has an issue...there is potential for forward-biasing back into the Vreg (death to the vreg!) during voice peaks, as Vcc can rise to twice the no-signal value, no?

What method to determine the modulation depth?

Yes, provided that a line is even present. The fact is that the source
circuit doesn't care whether it's connected to a line/load with all the
attendent forward and relected waves, or just a dull old R-L or R-C
circuit; at a single frequency, it can't tell the difference.

Again I agree. One can calculate all the voltages, currents, and powers
everywhere in the system, and get consistent and correct results. But
you can remove the transmission line entirely, so that you have no
reverse power, and no forward or reverse travelling waves, and yet have
exactly the same dissipation in the source and load resistors, and power
delivered by the source. As far as the conditions at the source circuit
connection are concerned, the only important result of all the wave
analysis is a single complex quantity: the impedance seen by the source.
That's all the source cares about, and it matters not one bit how it
came about. The source doesn't know or care how much energy is bouncing
around in the line, or even if it's connected to a transmission line at all.

> With that, I wish you all a Merry Christmas and Happy Holidays. I'll be off
> for awhile (unless the impending fractal optimization is posted)

chuckle No need to hold your breath. Have a good holiday, Steve.

Roy, Steve has not been able to prove his is a true statement. In fact, I have proven it to be false. Can you prove it to be true? Do you think two AND ONLY TWO waves of 100V at 2A each can be added together to get 200V at 4A? Don't you wonder where the energy goes in the two reflected waves that are predicted by the superposition principle but Steve completely ignores?

In any energy transfer system, if the following is the only possibility:

```
+--------------------------------+
| Dynamic Storage Only |------> Energy Out
Energy In----------->| |
(zero energy out) | No Static Storage |<------ Energy In
+--------------------------------+
```

Doesn't any and all energy eventually flow toward the out port since none of it escapes from the in port on the left? What am I missing?

4517. Re: Imaginary Reflections?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-11 22:28:43 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <uvff16g4lmoo9d@corp.supernews.com>
Source record: 129356

TDR is a valuable technique with many applications. And although the principles of travelling voltage and current waves are the same for any waveform, the equations used for steady state sine wave analysis are simplifications of the general principles. So a great deal of care should be taken in extrapolating from what you observe on a TDR system to a steady state system. For example, a complex reflection coefficient can be calculated for a single frequency, and any terminating network having the same impedance at that frequency will produce exactly the same steady state reflection. But various networks all having the same impedance at one frequency will produce different time domain reflections (or different steady state reflections at different frequencies). Meaningful reflection coefficients for time domain analysis can only be derived from purely resistive terminations or discontinuities.

Another very important difference between TDR and steady state systems is that the source of a TDR is generally turned off (for pulse-type TDRs) or in a quiescent state (for step-type TDRs) when the reflection returns. The result is that the reflection sees a passive load equal to the source impedance. If the source is matched, the reflection will be absorbed by the source resistance(*). In a steady state system, the source is actively producing a signal, so the reflected waves don't just see a passive resistance. This is the reason for the total re-reflection from the matched source in an example I've presented several times.

Roy Lewallen, W7EL

(*) I'm being a little free and loose here, and only entirely accurate with regard to purely resistive source and transmission line impedances. When either or both aren't pure resistances, the condition for impedance matching in the usual sense isn't the same as the one for minimum reflection. If a transmission line has impedance R + jX, the load is considered matched when its impedance is R - jX, since this is the condition for maximum power transfer with a variable load impedance. However, the reflection is eliminated when the load impedance is R + jX. So in a single-frequency system you've got your choice between maximum power transfer or minimum reflection, but you can't have both if the line Z0 is complex. In the time domain (that is, TDR systems), eliminating a reflection when the line isn't purely resistive requires that the impedance of the load be the same as the impedance of the source over the whole range of frequencies contained in the TDR pulse or step. Fortunately, even very lossy transmission lines look essentially resistive over the range of frequencies excited by most TDR systems.

OK, let me see if I understand now...

Using the I Smac hypothetical:

Initially, the 100 watt transmitter attempts to deliver it's full output to the load, since it has no clue that the load is not matched to the source. When the energy hits the mismatch, a portion of it, 10 watts, is reflected back to the source, 180 degrees out of phase. This signal, being out of phase with the source, opposes 10 watts worth of source energy from subsequent waves, so the source only puts out 90 watts once the reflected waves reach it. Further, once the reflected wave reaches the source, it is re-reflected back toward the load after undergoing another phase inversion, so, the wattmeter will now read 100 watts forward, since the re-reflected signal is now 360 degrees out of phase... Meanwhile, the source is only supplying 90 watts and the load is dissipating 90 watts, so 10 watts is "standing" in the line... If I'm correct, that would be the "standing wave".....?

Well, not really, but you will have to get out and change the antenna
for each band. You can use a single 10 meter stick, with a few extra
stinger whips for each band and work 20-10 quite well. And the 20m
performance of the 10m stick and longer stinger is better than most
"20m sticks". I use a 20m stick with a 4 ft stinger for 40m quite a
bit. It works great, and about as good as my "bugcatcher" style
antenna. What kills the average "hamstick" performance is too short a
stinger whip on top. Also the "fat" coil versions are generally better
than the "slim" sticks. Also where the windings are for the "loading
coil" effect performance to quite a degree. The better sticks maximise

the "loading" windings towards the top, instead of a steady pitch the whole way along the stick. That improves current distribution a good bit on the lower bands. I use only two "stick" antennas and cover all bands. My original antenna is a heavily modified 5 ft tall 11m firestick CB antenna with the middle cut out and a fat 80m coil inserted. By tapping the coil, or changing stingers, it works all bands 80-10. And due to the large coil, it has bugcatcher performance. On 80 or 40 it uses a 4 ft stinger whip. So it's about 9 ft total. I can keep up with nearly anyone on 80 or 40, unless they have something really hard core cooked up with very tall masts, etc. BTW, I often add extra lower masts to the antennas when parked. Gives a large increase in performance. The screwdrivers are good antennas. The only thing I don't like about them, is it's hard to easily add lower masts to them. In many cases, the coil sits too low for my tastes. My fave HF antenna is the regular old bugcatchers. For brute performance, and ease of mast length modifying, etc, they can't be beat. But, you gotta get out to change bands...That doesn't bother me though. I don't use those though as they are so heavy and require such a heavy duty base. So I make "plastic bugcatchers" that weigh a fraction of a bugcatcher and have about the same performance. My antennas didn't cost me a thing. All made from junk sticks, etc. I've got a pile of old antennas, masts, stingers, etc I keep just to experiment. The hustler quick disconnect I use is the most expensive part...:/ MK

Jes' ease back on the hammer of that shootin' arn. Nice an' easy. That's it. Take a deep breath. Ok. Now put the gun down, and we can talk.

You, I, and Steve all understand conservation of energy, and none of us would ever propose to violate it. I read Steve's statement (that you quote) to say that the forward power can be calculated entirely from the forward traveling voltage and current waves. And that the result you get doesn't depend on the values of the reverse traveling waves, or the reverse or total power. That is, once you calculate the value of forward power from the forward voltage and current waves, you don't modify the result based on the values of the reverse traveling voltage and current waves, the applied power, or the reverse power. Don't you agree with this?

Of course, we all know that when all the calculations are complete, the law of conservation of energy has to be satisfied. No one has said it's not.

Now we return you to your regularly scheduled showdown.

Be very careful there. Energy is a scalar and doesn't have phase.
Energy is a scalar as is water. What's the phase of water flow?

The voltage and current from the source are in phase. The reflected
voltage and current are 180 degrees out of phase. If the voltages
add, the currents subtract and vice versa.

I agree but that's not what Steve said. Saying that "forward power can be
calculated" and saying that "forward power consists only of P1 and P2"
are completely different statements. The reason that the result doesn't
depend on the reverse traveling waves is that they are redundantly related
through the reflection coefficient. That fact doesn't make the energy in
the reverse traveling waves disappear from the universe.

Here is what you agreed with, Roy. "This DOES NOT require a corresponding
destructive interference process ..." This statement contradicts what Steve
said in his QEX article: "When the system reaches steady-state, the two
rearward traveling waves at the match point (rearward waves 1 and 2) are
180 degrees out of phase with respect to each other and a complete
cancellation of both waves occurs."

Wave cancellation and destructive interference are the same thing.
The destructive interference is between two reflected waves each possessing
energy. The energy can be canceled in the rearward direction but it cannot
be destroyed. In a transmission line, there is only one result - constructive
interference energy in the other direction, i.e. re-reflection of the energy
in those two waves which Steve will admit are reflected energy waves that he
simply chooses to forget about.

The components predicted by the superposition principle at a match point are:
1. Pfwd1(1-Rho^2), unreflected power, same as Steve's P1
2. Pref2(Rho^2), re-reflected power, same as Steve P2
3. Pfwd1(Rho^2), reflected power involved in wave cancellation
4. Pref2(1-Rho^2), reflected power involved in wave cancellation

Steve completely ignores the energy in the two waves involved in the wave
cancellation. That's a violation of the conservation of energy principle. Do
you agree that Steve should ignore half the energy components predicted by the
superposition principle and add the other two energy components to get the total
power? He obviously does that to disguise the fact that all the reflected power
is re-reflected. Do you really agree with Steve that
75 joules/sec + 8.33 joules/sec = 133.33 joules/sec?

I have a rebuttal to Steve's QEX article on my web page at:
http://www.qsl.net/w5dxp/waves2.htm

On Wed, 11 Dec 2002 14:28:43 -0800, Roy Lewallen <w7el@eznec.com>
wrote:

|TDR is a valuable technique with many applications. And although the
|principles of travelling voltage and current waves are the same for any
|waveform, the equations used for steady state sine wave analysis are
|simplifications of the general principles. So a great deal of care
|should be taken in extrapolating from what you observe on a TDR system
|to a steady state system. For example, a complex reflection coefficient
|can be calculated for a single frequency, and any terminating network
|having the same impedance at that frequency will produce exactly the
|same steady state reflection. But various networks all having the same
|impedance at one frequency will produce different time domain
|reflections (or different steady state reflections at different
|frequencies). Meaningful reflection coefficients for time domain
|analysis can only be derived from purely resistive terminations or
|discontinuities.

And even here, line attenuation will affect the apparent reflection
coefficient.
|
|Another very important difference between TDR and steady state systems
|is that the source of a TDR is generally turned off (for pulse-type
|TDRs) or in a quiescent state (for step-type TDRs) when the reflection
|returns. The result is that the reflection sees a passive load equal to
|the source impedance. If the source is matched, the reflection will be
|absorbed by the source resistance(*). In a steady state system, the
|source is actively producing a signal, so the reflected waves don't just
|see a passive resistance. This is the reason for the total re-reflection
|from the matched source in an example I've presented several times.

Another method of TDR is used by HP, Wiltron and I'm sure others in
their vector network analyzers.

A measurement is first made in the frequency domain using a fairly
wide frequency sweep. The measurement response is then converted into
the time domain by using FFT. The various discontinuities are then
presented separated in time.

There is a problem with this technique when relatively narrow-band
devices are measured since to get good time/distance resolution a wide
sweep is required. If the narrow-band device doesn't pass the
necessary frequencies then there is an error. There is similar error
with TDRs using fast rise-time steps or pulses too, however.

One useful feature of the FFT method is that gating can be used to "remove" selected time domain responses and then the FFT applied again to re-convert to the frequency domain.

Another feature of the technique is that, unlike conventional TDR, transmission (two-port or through) measurements are possible. I have done open-field antenna measurements using time domain gating to remove reflections from ground or other objects, or to position absorber material to attenuate the reflections.

It is not uncommon when making swept-frequency measurements to see nulls in the reflection coefficient. Whenever you see this it is a clue that there are multiple reflections in the system, separated by distance. As the frequency changes, the reflection coefficients phases change at different rates. When they are out of phase a null or partial null is created. *Our old friend "reflection cancellation" in action.) Moving a gate around can help identify or remove individual discontinuities.

Be even more careful. Power is a function of time. In a steady-state sinusoidal system, its waveshape is that of a sine wave plus a DC term, with the sine wave frequency being twice the frequency of the voltage or current. Energy is the time integral of this quantity, so it's also a function of time. The energy waveform will be another sine wave of the same frequency as the power waveform but shifted 90 degrees, superimposed on a ramp.

The DC value of the power waveform is the average power. If the voltage and current are in phase, the entire power waveform is greater than zero, indicating that power is flowing only in one direction for the entire cycle, although its magnitude is going up and down sinusoidally, two cycles for every voltage or current cycle. If the voltage and current are 90 degrees out of phase, the power waveform will be centered around zero watts, meaning that power is flowing in one direction for half the time, and back the other way for the other half, resulting in no net power flow. The average in that case is zero, and the slope of the energy waveform ramp will be zero. That is, energy will flow back and forth in equal amounts each half cycle just like the power, but 90 degrees out of phase with it.

This is high school trigonometry, not rocket science, from a simple multiplication of v(t) times i(t), where both are sinusoids of the same frequency. (The integration for the energy waveform does require high school or freshman college calculus, or a little time spent with some graph paper.)

But this doen't make power and energy phasors, because phasors assume a particular frequency (that of the voltage and current), and the sinusoids involved with power and energy aren't at that frequency. But you could, if you had any reason to do so (and I can't think of one right off the bat), describe power completely as a DC term plus a sine wave of a particular amplitude and phase. But these waveforms are neither scalar nor phasor quantities as those terms are used in AC phasor analysis, and can't be mixed in with scalar and phasor quantities for analysis. (Unless, of course, you need to "prove" something that isn't so, in which case it's often useful -- essential, even -- to mix incompatible quantities and perform invalid operations.)

People often mean "average power" when they say "power", and you sometimes even see power "defined" as V*I*cos(theta), where theta is the phase angle between V and I. It's not. That's the *average* power. Power is v(t) times i(t), period. Average power is the DC term you get from the multiplication(*), and it's a constant in a steady state system. But

when you start talking about energy sloshing around in a transmission line, you have to deal with how energy and power vary with time. And you can bet your family joules that they do.

Roy Lewallen, W7EL

(*) The definition of average for any repetitive waveform is 1/T * Integral from t to t+T of W(t) dt, where W(t) is the waveform and T is the period. For power, W(t) = v(t)*i(t). This holds for any repetitive waveform of any shape. But for sinusoids, when you multiply v(t) and i(t) you get two terms, one a constant (DC) and the other a sine wave (of twice the V and I frequency). The average value of a zero-centered sine wave is zero, leaving the DC term as the average value by inspection. You'll get exactly the same result if you calculate it from the definition of average.

Sorry, Cecil, I'm not going to get sucked into whatever ongoing problem
with what you think Steve said in some article in the past.

And I'm satisfied I read Steve's statement correctly.

You'll have to scare up your posse somewhere else.

Roy Lewallen, W7EL

Hi Steve,

Odd this simple fact was overlooked by all - even with all the "take care" being taken.

The reflection at the plane of discontinuity enforces a phase shift, BUT that phase shift is not what appears at the source because the transmission line then imposes its own phase transform equal to the number of degrees long (electrical length) that the line is from the plane of reflection back to the plane of measurement (the source).

This has been a point our other Steve (VE9SRB) has been repeating to no end in terms of adding currents and voltages, not power. Powers add only at the most specific of conditions (yours is not one of those occasions).

> Further, once the
>reflected wave reaches the source, it is re-reflected back toward the
>load after undergoing another phase inversion
This is sheer speculation (that the source is not matched) and again ignores the line's contribution of reflected power back to the source, now a complex load (if not matched to the line). Even IF the source is mismatched, I dare say few here are competent to determine its actual value (although I've seen considerable speculation to force fit the arguments presented in too many threads through the years).

When both ends are mismatched (your and other's assumption) and the line length is not known, there is no way to accurately measure how much power is being developed in the system. This is known to Metrologists as Mismatch Uncertainty and equals ï¿½25% of the actual power for the simple expectation you portray (which, of course, is easily twice the power you think is in the reflected component).

Thought experiments of an unmatched source supporting complex power scenarios through unspecified transmission line lengths to another, remote mismatch are dead on arrival.

Your request is similar to "RF ID" systems.

Search:
www.google.com/search?q=RF+ID+power+transmission

The above link will take you to plenty of reading material. The .pdf files are often very good - typically 'White Papers' on the subject at hand. I haven't checked these results.

My car keys work on this sort of a system (I suspect higher power), but only about 1cm. The apartment building that we are currently living in has little tags that reach several inches. The garage door tag and a commuter pass both reach tens of feet, but have built-in batteries. (I seem to have a lot of these sorts of RF ID type tags.)

Can you integrate the power (capacitor) and use the 72mW just in a short burst ? I'm not an expert in this, but 72mW seems like it might be towards the high end for what you're proposing. I do know that the designers of RF ID systems will make huge efforts to reduce the power requirements.

If you've really interested, then you could search the US Patent Office (although many patents are intentionally as clear as mud). You'll need a TIFF reader to see the images.

We don't have to worry about that in transmission lines. Forward power
has the voltage and current in phase and reflected power has the voltage
and current 180 degrees out of phase so V*I = power (no vars) because
cos(angle) is always +1 or -1 depending upon whether it is forward or
reflected power. Forward waves and reflected waves are transparent to
each other and pass unmolested until they both encounter an impedance
discontinuity where their wave components can cause interference.

My point exactly, Roy. Do you agree that a forward wave of 61.24V at 1.225A has an associated average power of V*I=75 joules/sec? Do you agree that a forward wave of 20.41V at 0.408A has an associated average power of V*I=8.33 joules/sec? Do you agree with Steve that these two (and only two) waves can be added to get 81.65V at 1.63A with an associated power of V*I=133.33 joules/sec? Do you agree that 75 joules/sec + 8.33 joules/sec = 133.33 joules/sec?

Steve says the average power contained in a wave in a transmission line is V*I = V^2/Z0 = I^2*Z0. I am basing my discussion of power on his equation. It is obviously average power.

No, when V and I are in phase, the power is V * I * (1 + sin(omega *
t)). The *average* power is V * I. (where V and I are RMS values)

> joules/sec?

Maybe. Depends. If I have two one volt voltage sources and a one ohm
resistor all in series, I can turn on one source and get 1 volt at 1 amp
for one watt in the resistor. I can turn that source off and turn the
other source on and get one watt in the resistor. Then I can turn both
on and get two volts and two amps for 4 watts in the resistor. So I've
added two "one watt" sources to get 4 watts. Pretty cool, huh?

Fortunately, your sources are capable of variable power outputs. Unfortunately,
a wave in a transmission line with a fixed voltage, a fixed current, and
a fixed ratio (V/I=Z0) doesn't have the luxury of varying its associated power.
V*I is all the power there is. There ain't no more (and no less). Conservation
of energy rules. A battery adjusts its current to its load. An EM wave in a
transmission line cannot do that. The energy, along with Z0, dictates the
magnitude of the voltage and current. The energy cannot increase without
another energy source. A 75W wave cannot add to an 8.33W wave to get a
133.33W wave. An additional wave, in this case in the form of constructive
interference, must exist to supply the additional 50W. It's all explained
on my web page at: http://www.qsl.net/w5dxp/waves2.htm
I can see how someone who hasn't read Dr. Best's article would be at a
disadvantage in understanding the subject matter.

Steve's two and only two waves are constant power, constant voltage, and
constant current (all averages). He says that's all there is, two and only
two waves. His two and only two powers add up to more power than is available
in those two and only two waves.

Hi Cecil,

By forward waves and reflected waves, I presume you mean two
independent waves from independent sources.

This is certainly the tenor of past discussion.

By transparent I presume you mean to express that the two waves
are insensible to each other as are the two independent sources.

No one would expect anything other in a linear medium.

By impedance discontinuity, I presume you to mean a change in the
V/I as a function of medium change.

For waves in a transmission line, splicing a 75 Ohm cable to a 50 Ohm
cable should do the trick. For waves in the ï¿½ther, penetrating into
soil, water, trees, what-have-you is all around us.

By interference, I presume you to mean to express that the two
waves are capable of mixing and producing new frequency products.

No way. Or:

By interference, I presume you to mean to express that the two
waves are sensible to each other and no longer independent.

Just what this interpretation actually means escapes me (if I allow
myself to neglect all the other extraneous business you find necessary
to create the interference).

If I see the projection of the sun through a double slit against a
screen, I will see light and dark bars due to "interference." There
is absolutely nothing here that requires an impedance discontinuity.
There is no causal effect enforced on either of the two slits, one on
the other (they remain independent sources). The two waves are wholly
independent of each other before they fall on the screen, and after
they reflect (there is no magic zero time at the screen to change
anything going on here).

So, just what kind of "interference" were you thinking of?

Hi Cecil,

Odd how you can fault Roy for his sources' variability and then deny
them their variability through a transmission line. What you describe
(the inability) is simply a function of time before the Steady State
is settled in (shorten your transmission lines if the time haunts
you). You could have as easily said the batteries were incapable for
their first few microseconds too.

Hohoho!

You should contact F2QG (Wincker-Force, or -France or -Fun... nevermind).
There's potential for a good European Antenna Troller Team!

Sure a dummy load is an ultimate, broad band minded, compact, perfectly
un-noisy solution too! Perhaps a little bit cheaper...

I assume that radio receives large portions of the VHF/UHF portions outside the ham bands? If so, that probably is a contributor to the interference. If it is a real annoyance, I would go with the DCI filters and buy a cheap scanner if you want to listen outside the ham bands.

>> (I suspect higher power), but only about 1cm.

"Richard Clark"
> You are off by three orders of magnitude in frequency:
>>>...at frequencies that are below the Mhz range if possible.

Actually, IIRC, my car key receives (power and signal) at about 100kHz. The key doesn't need to contain a battery. Some do - but *only* for the remote control functions - both RF transmit plus an IR LED (the extra thin wallet backup key doesn't contain a battery).

The incoming 100kHz signal is modulated with a rolling code, the key thinks about it and responds (via an LED) with the appropriate coded signal back. If everything matches, then you can start the car. It is about as secure as is practical and even results in a discount on the insurance. On the other hand, a replacement key costs several hundreds, plus the labour to program it into the system.

Anyway, pretty sure my car key is getting the power+signal at about 100kHz. As I mentioned, only about 1cm. Pretty much a 'transformer' system.

IIRC, there are some other "RF ID" systems that use the same frequency range (sub-MHz) over longer ranges.

PS: he did write "if possible", so I didn't think other higher frequencies commonly used in RF ID systems would be automatically disqualified as a potentially helpful answer. His biggest problem will be the 72mW over 18 inches - assuming that he wants a low power system.

Tom, we had a similar problem at work with 929 MHz paging and a telemetry system receiver on 928.8 MHz. There was no way we could possibly notch the 929 MHz stuff with a cavity and still hear anything. So we changed antennas.

Get yourself a good, horizontally polarized antenna. Make it a yagi and pay special attention to ensuring that the antenna is properly balanced and matched. You'll get around 20 dB of rejection of pager signal right there, more if you point away from the pager antennas.

You might also take a close look at how you have grounded the antenna. Make sure all your ground connections are tight, clean, and properly protected from oxidation.

Good Luck!

Jake Brodsky, AB3A mailto:frussle@erols.com

From: Richard Fry <rfry@adams.net>
Message-ID: <f01K9.307$Xd.242316@newsfeed.slurp.net>
Source record: 129244

Previous post (buried deeeep in an earlier thread):

>"But you can remove the transmission line entirely, so that
>you have no reverse power, and no forward or reverse travelling
>waves, and yet have exactly the same dissipation in the source
>and load resistors, and power delivered by the source."

This same individual echoes this concept in another post:

> "Yet if you connect the transmitter to a 450 ohm load
> through a half wavelength of 450 ohm line, the line's SWR is 1:1, the
> reverse power is zero, and the transmitter will be very unhappy. It's
> unhappiness has nothing to do with SWR or reverse power -- it's unhappy
> because it's seeing a 450 ohm impedance. The transmitter's SWR meter
> will incorrectly report an SWR of 9:1, even though the transmission line
> SWR is really 1:1."

Reverse power is not zero from the transmitter's perspective. It is zero only at the interface of the line and antenna, and consequently also zero in any length of the line itself. The transmitter is unhappy because power is being reflected back into it by the 9:1 mismatch at its output terminals, rather than being sufficiently accepted by what is connected there.

Reflected power and forward power combine as a vector sum, and the max value of this sum can damage components not rated for it. Reflected power does not have to travel through some length of transmission line to create "standing waves" to damage components. Standing waves do not damage components, excess power does. Standing waves are just an artifact of the two RF waveforms traveling in opposite directions through a sufficient electrical length of line. Whether or not they develop is irrelevant to the amount of damage that the reflected power may cause, when added to forward power. The reflected power from the 9:1 mismatch in the above situation likely will damage the transmitter (NOT the line or antenna). The tx SWR meter SHOULD see this high mismatch, and protect the tx. The tx meter is NOT incorrect, it is telling the truth about what is connected to the tx output connector.

It doesn't matter to the tx if a given mismatch is bolted right on the tx output connector, or produced by an antenna-to-coax junction 1,000 feet up a tower. The potential for damage to the tx by the addition of that reflected power to the forward power will be the same for both cases.

Richard Clark, KB7QHC wrote:
"And the SWR meter is between the isolator and the load?"

These forward/reflected power discussions come around again and again. Related items introduced to support assertions result in confusion, judging from replies which follow.

Bird Electronic Corporation published a "Bird Technical Series". I long ago asked Bird for copies of the series and they sent them to me.

In the paper called VSWR, Bird says: "A simple algebraic subtraction (Pfwd - Prefl) yields the net power delivered to the load."

Let that sink in, and everything it means. If it were untrue, the Bird wattmeter would not work as it does.

Many assertions made in this thread don`t square with the simple equation Bird gives. Bird`s proposition is simple: A near lossless line and the power delivered to the load is the same as that delivered by the transmitter to the line. Statements contrary to the above in the macro, steady-state sense are simply wrong.

Want to know how transmission lines and the Bird wattmeter work? Write to Bird and ask for the "Technical Series". I hope they still have copies.,

Best regards, Richard Harrison, KB5WZI

> because it's seeing a 450 ohm impedance. The transmitter's SWR meter
> will incorrectly report an SWR of 9:1, even though the transmission line
> SWR is really 1:1."

Reverse power is not zero from the transmitter's perspective. It is zero
only at the interface of the line and antenna, and consequently also zero in
any length of the line itself. The transmitter is unhappy because power is
being reflected back into it by the 9:1 mismatch at its output terminals,
rather than being sufficiently accepted by what is connected there.

Reflected power and forward power combine as a vector sum, and the max value
of this sum can damage components not rated for it. Reflected power does
not have to travel through some length of transmission line to create
"standing waves" to damage components. Standing waves do not damage
components, excess power does. Standing waves are just an artifact of the
two RF waveforms traveling in opposite directions through a sufficient
electrical length of line. Whether or not they develop is irrelevant to the
amount of damage that the reflected power may cause, when added to forward
power. The reflected power from the 9:1 mismatch in the above situation
likely will damage the transmitter (NOT the line or antenna). The tx SWR
meter SHOULD see this high mismatch, and protect the tx. The tx meter is
NOT incorrect, it is telling the truth about what is connected to the tx
output connector.

It doesn't matter to the tx if a given mismatch is bolted right on the tx
output connector, or produced by an antenna-to-coax junction 1,000 feet up a
tower. The potential for damage to the tx by the addition of that reflected
power to the forward power will be the same for both cases.

Nope, they are from the one and only source in the system and are coherent.

> By interference, I presume you to mean to express that the two
> waves are sensible to each other and no longer independent.
>
> Just what this interpretation actually means escapes me (if I allow
> myself to neglect all the other extraneous business you find necessary
> to create the interference).

Being "sensible" to each other is what allows destructive interference
between components of two different coherent waves traveling in the same
direction.

The basic question is: What happens to the energy in two waves that
engage in destructive interference such that the total voltage goes
to zero and the total current goes to zero? In the example presented,
the energy traveling toward the source obviously goes to zero along
with the voltage and current. But since energy cannot be destroyed,
where does that energy go?

> If I see the projection of the sun through a double slit against a
> screen, I will see light and dark bars due to "interference." There
> is absolutely nothing here that requires an impedance discontinuity.

There are certainly other kinds of interference rather than two out-of-
phase waves traveling in the same direction in a transmision line. What
is your point?

> There is no causal effect enforced on either of the two slits, one on
> the other (they remain independent sources). The two waves are wholly
> independent of each other before they fall on the screen, and after
> they reflect (there is no magic zero time at the screen to change
> anything going on here).

This is obviously not the kind of interference being discussed here.
The kind of interference being discussed here results in the loss
of identity of the two superposed waves thus creating a new wave. We

are talking in particular about destructive interference of two coherent reflected waves traveling in the same direction, the same thing that happens with non-glare picture glass.

> So, just what kind of "interference" were you thinking of?

The interference established by two coherent waves traveling in the same direction in a transmission line. Please reference: http://www.qsl.net/w5dxp/light.gif

In Dr. Best's analysis, his two sources are coherent waves, not transmitters
and not batteries. Dr. Best's asserts that the power in his source waves is
fixed at V^2/Z0 = I^2*Z0 = V*I? Do you agree with Dr. Best?

Exactly, Richard. When one chooses to use the reflection model, one must
stick with the reflection model throughout the entire analysis and not
switch to the circuit model in mid-analysis.

Is your "40 meter long jacketed copper wire" a single wire? If so,
you cannot consider it to be a transmission line and must consider
it to be part of your antenna. If it's a single wire, it will have
a large effect.

You certainly missed the curve on that one. As I said, I would only
consider it if I were to ignore all the other business that is wholly
unnecessary to this "interference."

>
>> If I see the projection of the sun through a double slit against a

Certain kinds? Do I have to ask you what kinds? It is all too tiring
to have to engage in 6 or 7 rounds to complete one simple answer.
Again you had a choice to talk around it or simply name ONE.

>
>> There is no causal effect enforced on either of the two slits, one on

Interference of two waves are not being discussed? Well, then there
is no point in further discussion.

If you want to actually build an antenna for immediate use, I
recommend that you follow a published design. The ARRL Antenna Book
has a family of such designs.

If you want to design antennas as an intellectual exercise then there
are a number of CAD programs that can be used.

There are commercial programs such as: EZNEC, NEC-WIN, Antenna Model,
etc.

There are a number of freeware programs that mostly use the NEC-2
engine. These include: MultiNEC and 4nec2. MMANA is also freeware
and uses the Mininec engine. A google search will locate all of
these.

In the early 90's there were several manufacture sponsored studies done on the safety of cell phones in different environments. The study was done in relationship to possible legal action if there were any problems or accidents that would leave the phone manufactures liable. I was working for Motorola CIG at the time and got to see the results.

All airplanes were shown to be somewhat affected by cell phone emissions, generally in the communications area, but not limited to that area. The planes worst affected were early model 737's, L1011's and first model Airbus's, according to one engineer AB was worried that they could crash due to cell phone usage as they are dependant on computer control. All the airplane manufactures supposedly issued modification procedures and supposedly all problem areas were corrected within three years. However the chances of problems caused by cell phone are deemed too high a danger so the are still banned during flight. And the fact that changes to both phones and planes make the probability of a problem too great.

As for hospitals same basic problems were shown, they can interfere with medical equipment. I was in the emergency room a while back when an accident victim was brought in. The cop decided to use his phone to call the station and it sent much of the equipment out of control till he had it forcibly removed and turned off. The hospital was planning on prosecuting the cop last I heard, as a heart patient nearly died because of this. The problems is that much medicial equipment isn't properly shielded for all levels of RF emissions.

The worst offenders phone wise are analog phones, tri-mode GSM (don't know why the tri-mode makes a difference) original CDMA phones in that order. The newer CDMA and TDMA phones are supposed to be the safest.

Hi Roy,

I am going back to this previous post as it seems to be the clearest
and most straight forward example.

My question is: with a watt meter at the output of the source and an
open half wave line connected to the other side, and the watt meter
reading 100 watts forward and 100 watts reflected, the resistor in
the source is dissipating zero power.

Remove the half wave line from the watt meter and you still have the
same conditions. The meter still reads 100 watts forward and 100 watts
reflected. The source resistor is dissipating zero power.

Could it be that there is no power involved here at all? In other
words the watt meter is reading 100 watts because of, and only because
of, the voltage it sees from the source and no current is
involved as evidence by zero dissipation in the source resistor.
There can not be any reflected power to the watt meter because there
is no line connected to it.

Thanks
Gary K4FMX

Hi Bill,

Take a picture of an antenna that is suitable, find the scale, apply
the scale. Only takes a ruler.

If you are looking for the "best" or want to "improve" something; then
you are in over your head as there is nothing simple about this for
someone who is not good in electronics or math. [The first hint of
this is that you want to design without the pain. Skip it, there is
nothing new about 50 year old yagis to warrant a new design or the
pain.]

OR

You can spend a few years with a modeler (the software you are looking
for) and discover that, yes, if you took a picture, found the scale,
and applied the scale you would do just as well in the long run. Some
of us find the software entertaining, but your mileage may vary.

If you want to descend into that vale of woe, visit:
http://www.eznec.com/
After a week, you will either stick with it, or you will buy a brownie
and film (cheap choices both).

Actually we do and as far as i remember, most aircraft have conventional ovens (the warmed up food you get is usually covered with and aluminium foil.) and trust me, even if it doesn't interfere with the nav systems, it interferes with the vhf comms. And in reply to someone saying that you can tune in to 111.9Mhz for example on your radio, it doesn't work that way, even tho it is fm, the frequency is modulated differently from the way a radio picks up a transmission. You'll never be able to "listen" even if you get the crystals on your radio tuned in. I'm sorry i'm attaching this to someone elses post but when i read these messages i wonder why ppl never listen to what they're told, until some incident happens... and bureaucracy is not an excuse!
one more thing i'd like to add is that the reason there haven't been recorded accidents is because most of time, the interference is more of a nuisance rather than life threatening, like off course navigation, background noise on the vhf comms, loss of and failure of flight management systems... Most pilots are able to cope but come on ppl, why wait for an accident before we learn? For once, lets not let some ruling be written up in blood.

If that's a problem, let me correct it. Please reference

http://www.qsl.net/w5dxp/fig2.gif

The transmitter source is somewhere out to the left, out of the
picture. The load is somewhere out to the right, out of the
picture. The energy inputs into the illustrated system are the
Pfwd1 and Pref2 coherent waves. The energy output from the system
is the Pfwd2 wave. This is what has been being discussed. So to
alleviate any confusion, I will differentiate between the "transmitter
source" and the "source wave(s)" from now on. I thought it was self-
evident up until now.

> You certainly missed the curve on that one. As I said, I would only
> consider it if I were to ignore all the other business that is wholly
> unnecessary to this "interference."

Please consider anything you want but please use Occam's Razor to
distill this discussion down to something managable. That is what
I am trying to do. Introduction of an infinite number of irrelevant
concepts is a well known diversionary tactic. Why on earth would
you not "ignore all the other business that is wholly unnecessary"?
What does the price of eggs in China have to do with this discussion?

> Certain kinds? Do I have to ask you what kinds? It is all too tiring
> to have to engage in 6 or 7 rounds to complete one simple answer.
> Again you had a choice to talk around it or simply name ONE.

I did name one, Richard. The particular kind of interference that I
am talking about is the interference between two coherent waves traveling
in the same direction in a transmission line. Any other kind of interference
is irrelevant to the discussion and I hope you agree we should avoid
irrelevant diversions.

> Interference of two waves are not being discussed? Well, then there
> is no point in further discussion.

Hmmmmm, exactly what Dr. Best says as we get closer to a truth that he
doesn't care for.

Why must you introduce reams of irrelevant material. Are you interested
in getting to the truth or interested in diversions? Would you please
answer the question that Steve has refused to answer?

In a transmission line containing a match point and reflections,
the reflected energy:
1. Flows into the transmitter
2. Stands still
3. Disappears from the system
4. Flows toward the load
5. Other, please explain _____

This discussion is limited to "source waves", Richard. Any deviation
from that topic is just another logical diversion. One wonders why
logical diversions are needed.

If you have forgotten, the topic is how Dr. Best takes two and only two
source waves and combines them to obtain more than the sum of the energy
in those two waves. Batteries and transmitter sources are irrelevant to
the discussion.

> That is two for two where you simply ignore the
> question and steamroller your agenda. No dialog in that.

The topic is NOT batteries or transmitter sources. The topic is source
waves. You seem afraid to discuss this topic. One wonders why.

Because your question is ambiguous. Are you talking about the system
load or the isolator load?

In a real-world source, there will always be dissipation in the
source. Your model doesn't represent any ham transmitter that
I know of. There is current flowing and it is heating up the
final. We are talking about RF. The charge carriers are always
moving, i.e. causing current even if it is only displacement
current.

Just a tidbit of information sourced from the GSM MoU Association.
The first commerical GSM service in the US was launched in November 1995 by
American Personal Communications and by 1997 there still were only 400,000
users. Therefore, before the end of 1995 there was no 1900mhz and therefore
no triband or triband phones for that matter. I would be suprised if there
any tri-band phones in 1995 (actually 1996) or even in 1997. So when exactly
was this study done (not just early 90's because that cant be accurate), and
if it was before 1996, then how did they use tri-mode GSM phones. I am not

argueing with you, there are just too many inconsistancies in this "study"
I have provided a link to back up what i wrote above

Source record: 129274

Hello,

First, thank you ALL for the info; it has been a great thread to read!

The transmitter can be of any power (within the law/limit). The receiving circuit (coil and/or antenna) needs to get only "raw" power (no information) to run a small micro (~5mA) and a sensor (~15mA) all at about 3.5 to 5 volts. Hence about 70+mW.

It could be done with about 40mW, but my practical side says prepare for something in between 40mW and 70mW with a little extra :-)

As far as the transformer version, I too think it is "the one". I need to do more research on air core coupled transformers?

I imagine that the frequency reaches a peak for proper coupled power into the load. But since I do not do radio engineering, I don't have intuition helping me... that's where the group comes in! There probably is a proper coupling frequency that matches everything just right. The only monkey in the circuit would be the fact that there may be more than one micro and sensor, i.e. one transmitter and multiple receivers, so the load may vary :-(

Again thanks for the ideas and info,

Aron

Particular kind? Substitution of your Particular for my Certain is
meaningless. You do nothing more than repeat an assertion and
introduce yet more argument (called steamrollering). Your rambling
requires me to buy into the incredible complexity and inspecifics you
have built into this. Like I said, I have no interest in pursuing
this 6 or 7 rounds. You have not distinguished between your
"Particular kind" of interference and these supposed others. Failing
that, there is no point in addressing even more complexity.

There's no current at either end of the line, but there's current in
between. And there's voltage at the ends of the line but the voltage is
zero exactly at the center of the line. This is a classic case of

standing waves.

There are voltage and current waves bouncing back and forth along the transmission line. From these, you can compute that 100 watts is traveling forward and 100 watts traveling in reverse. If the length of the line is, say, 150 ns (about 100 feet of solid polyethylene dielectric coax), this represents 100W * 150ns * 2 = 30 uJ of energy. And, sure enough, when we first turned on the source, it produced 100 watts for the first 300 ns -- 30 uJ of energy. But after that initial 300 ns, the current from the source dropped to zero, so there's no current -- or power -- entering or leaving the line.

The reason there's a total re-reflection at the source is that the returning waves see one end of the source resistor, and at the other end there's a source producing exactly the same voltage. Since the source resistor has the same voltage on both ends, no current flows through it, so it looks just like a passive open circuit. Once you've reached the steady state condition, you can change the source resistor to any value or disconnect the source altogether and maintain the same conditions in the (lossless) line.

The same illustration can be made with a current source in parallel with a 50 ohm resistor driving a *short* circuited half wavelength line. Exactly the same thing happens, but with the voltage and current reversing roles. The returning current wave encounters an equal but out of phase current from the source (unlike the voltage wave which was in phase -- due to the phase reversal of current when reflected). The top of the shunt source resistor sees two equal currents in opposite directions -- one from the current source and the other from the line. That is, all the current from the current source goes into the line and none into the shunt resistor. The shunt resistor has zero volts across it, so has no dissipation. What the returning waves see at the input end looks like a passive short circuit, so they're totally reflected. Once steady state is reached, the source resistor can be changed to any value without changing the line conditions. Or the current source and resistor can be replaced by a short circuit. The voltage at the ends of the line is zero, and the current at the center of the line is zero.

Message-ID: <uvhqqu3k6qhe55@corp.supernews.com>
Source record: 129279

The reason I didn't attempt to model a transmitter for my example is that it would surely invoke another long string of arguing over what constitutes a good model for a transmitter and distract from the question at hand. No matter what I would propose for a transmitter model would bring (likely valid) objections as to its accuracy, and these would be used to dispute any conclusions that might be drawn. And my model contains a lossless transmission line, which can't exist in the real world either. Athough the situation I've described can't exist (like any of the examples in just about any circuits, electromagnetics, or antenna textbook), I think it's very useful in gaining an understanding of what happens in more complex circuits. The alternative is to throw up your hands and say something like "transmitter gods work in mysterious ways beyond our understanding", believe whatever you choose, and make no attempt at understanding what's happening. I know that a sizeable number of readers prefer this approach to knowledge -- that's fine. My writings aren't intended for you.

If reverse power is not absorbed in the source resistor in the simple circuit I've used for illustration, where the source is perfectly matched, what could there be about a transmitter which would cause it to absorb the reverse power?

Again I'll mention Wes' example of a generator having an isolator at the output, where the dissipation in the isolator equals the reverse power. Unlike the simple circuit I used for illustration, it does present a matched passive load to the returning waves. Do you feel that's a good model for a typical amateur transmitter? What evidence is there for it?

Hi Roy,

Why is this a problem of a transmitter given it does evidence this conjecture of reflected power, and your model, extremely specific and by nature not of nature at all, not showing it? You have only thrown the problem backwards into the source behind it. The whole point of the historical introduction of Thevenin sources was to escape these non-intuitive formalisms that lead to recursive paradox.

Of the strangest assertions is to maintain that Reflections due to transmission lines and lumped circuits are indistinguishable, and then progressing to the next step to say that reflected power in transmission lines does not exist (except when an isolator conspires to re-route it to a dissipating load - an admission that further confuses the message).

I would challenge anyone here to reproduce your thought experiments' results at the bench inside an enclosed volume that could be calorimetrically measured to evidence a lack of heat generated from such circumstances. Would an open circuit load to a transmitter/source (of any design) fail to show a temperature rise as a consequence? More to the matter: does this bear out on the bench? And for that matter, a short is as much a discontinuity as an open, produces reflections just as well, and seemingly offers a contradiction to the argument for a lack of power in a reflected wave.

As Steve has offered so many times, the phase is far more important as a general answer than these crafted solutions.

None. They're measurements of two different things.

The SWR is the ratio of the highest to lowest voltage (or highest to lowest current) along a transmission line that's at least a half wavelength long. The AC power factor is the ratio of average power to the average of the product of RMS voltage and current in an AC circuit.

The ratio of V to I of the traveling waves in a transmission line is equal to the characteristic impedance of the line. At MF and above, the characteristic impedance is almost purely real (resistive), so traveling wave V and I are in phase. If you're inclined to calculate the power contained in the traveling waves in a transmission line, you'll find that the power factor is very nearly one. The SWR results from interference between these traveling waves, and is not something that affects the traveling waves or their characteristics.

I am looking for ferrite beads that will fit over LMR600 (0.590 inches diameter). I have tried Amidon, but they don't carry anything that large, and the beads that are close to this size are mostly out of stock.

I want to prevent currents on the shield, but the LMR600 (solid core) I have is much too stiff to coil into a choke.

Are there any other sources for large ferrite beads?

Thanks.

AC power factor is defined as the degree to which voltage and current are in phase, quantified by the cosine of the phase angle by which the current leads or lags the voltage.

Power consumption of a 1-phase AC load = E * I * power factor. For a 3-phase load it is E * I * SQRT(3) * power factor.

4600. Re: Highest mobile antenna on your car and still be legal

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-12 21:10:37 UTC
From: "David G. Nagel" <nagel@core.com>
Message-ID: <3DF8FB4D.4BAF49FB@core.com>
Source record: 129289

Most states limit the height of any vehicle on the highways to 13 feet 6 inches above the roadway. Bridges are constructed to meet this height plus a few inches for safety. Special movement permits and routing are needed to exceed the max legal height. This applies to all vehicles on the highway, trucks and cars.

Hi Roy,

With the watt meter essentially at the end of the line, as you say
there is no current there, how
can the watt meter read reflected power with no current? (no line
connected) And we can't
really say that the watt meter is looking at a 50 ohm line anymore
with an open circuit right at
the meter. The current maximum would be a quarter wave back towards
the generator. With
essentially zero line length there is no room to develop a standing
wave.

I suppose that it could be argued that because the meter is calibrated
to operate at 50 ohms that
is what it is assuming. But I would think that it could also be argued
that because it does not see
50 ohms that it is no longer reliable. And that it is only coincidence
that it is reading what it does
in this situation?

Being that the watt meter reads voltage from both directions at once
(can't distinguish voltage
direction) it relies on current direction to tell whether power is
forward or reverse. If there is no
current at this point it can not tell us if there is reflected power
or not.

That is why I am wondering if the watt meter is really responding more
to a mismatch condition
than it is really telling us about reflected power.

Source record: 129291

You will find that any vehicular antenna height greater than
about 12 -12.5 feet will have many "encounters" with tree limbs,
etc. This effect also changes with the seasons; less banging
when the trees are bare.

A top hat (capacity hat) is worthy of consideration in reducing
the height and maintaining acceptable performance.

73,

Tom N4TAB

4604. Re: AC PF & SWR ??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-12 22:03:02 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <uvi1t6ij7auee4@corp.supernews.com>
Source record: 129293

Good questions.

1. For a lossless line, changing the line length doesn't change the SWR. If you want to calculate the SWR from its definition, you need to have a line that's long enough to guarantee that you have at least one maximum (that is, point where the voltage or current is the greatest it can be) and one minimum (likewise). This requires at least a half wavelength of line, which is the only reason I made that qualification. But if you shorten the line, there's no change in the forward or reverse traveling waves which interfere to create the standing waves, so the SWR (as the term is universally used) remains the same. It's just that you can no longer reliably determine it by looking at the maximum and minimum voltage or current points. You can still calculate the SWR from the reflection coefficient at the load, or the cable and load impedances. Or you can indirectly measure it using a directional coupler approach.

If a line is lossy, the SWR decreases as move away from the load. But nothing magic happens at a half wavelength.

2. There's a problem with answering the second question. The problem is how you define which direction constitutes positive current. If you define the direction of positive current flow to always be from the source to the load, then what I said in my previous posting has to be modified. In that case, the voltage and current are in phase in the forward traveling wave, and out of phase in the reverse traveling wave, because the direction of the currrent is reversed in the reverse wave. (In fact, Bruene-type directional meters use this phase difference to separate forward and reverse components.) If you calculate a power represented by the traveling voltage and current waves, voltage and current out of phase represents power flowing in the opposite direction from the direction considered to be positive for current flow.

But this doesn't answer the question of whether the actual voltage and current (the sum of the forward and reverse traveling waves) can get out of phase along the line. I don't have a ready answer for this, and can't see one intuitively, so I'd have to sit down for a while with some equations (or a spreadsheet or simple program) to get a feel for what happens to the phase of the sum of forward and reverse waves. I don't have the time for it just now -- maybe someone else can answer it. I don't see that the phase of the combined voltage and current waves has any special significance.

Wind coax on the core or rod, or slip cores over a piece of coax, leaving a small amount of coax at each end of the choke. Tie the center conductor to the shield at each end. Connect one end to the ground side of the antenna analyzer connector and the other to the center pin, and measure the impedance.

The impedance of cores slipped over the coax will increase in direct proportion to the number of cores. That is, doubling the number of cores will double the impedance. The impedance of a winding on a toroid core will increase as the square of the number of turns -- doubling the number of turns will increase the impedance by a factor of four. On a ferrite rod, the impedance will be more than proportional to the number of turns, but less than the square of the number of turns, with the exact factor depending on a number of things related to the rod and winding geometry and the rod permeability. You can use these rules to extrapolate if it's not convenient to measure the exact configuration you'll be using.

Well, it's a magical meter. We need to be careful in mixing real meters with idealized situations. If it does bother you, though, move the meter just a tiny way in from the end, where neither current nor voltage is zero. Any real wattmeter would absorb energy from the line, too, which would have to be replenished by the source and which would disturb the assumed conditions.

You're right that a typical directional wattmeter is responding to a mismatch condition, although a 50 ohm wattmeter inserted in a 50 ohm line will correctly indicate the same forward and reverse power you get from calculation of these quantities from the voltage and current waves on the connected line. A 50 ohm wattmeter inserted in any other impedance line won't indicate the forward and reverse power on the line it's connected to, though. A directional wattmeter can't tell if it's connected to a 50 ohm line, a line of another impedance, or simply a circuit of lumped components. As long at the impedance seen by the wattmeter is the same, it'll indicate the same forward and reverse power. You can conceptually understand what it's doing by imagining that it contains a short piece of 50 ohm line and that it's indicating the forward and reverse power on that line. Some wattmeters, like the Bird, actually have such a line physically inside. Others like the Bruene circuit, don't.

Hi Doc,

No yet (I even didn't know them until you ask me to chekc them ;-))
But seems interesting, maybe similar to Hi-Q.
I will check their website (which is temporary - I hope -
inaccessible.
In the meantime I printed the eham reviews.

NB. About Hi-Q, Charlie confirmed me he provides 4 magnets to place
his Hi-Q on a car roof top. But his antenna are expensive : a 2.4/40
RT motorized + capacitanc ehat + large coil + shipping to europe =
about 550$...

Thanks for yr help

You can also find them called skeleton discone antennas as
well.
It is a variation on the discone where the elements
represent a
plane cross section which cuts through the vertical center
of
the discone.

Hi OM,

> scientific proof of the Earth passing through the Photon Belt
Um, I think this occurs for half of earth half of every day.

I can't imagine how this gets better, but it does help quick analysis
and saves time when the presenter offers to take his cyanide tablet
before stepping up to the podium. Hopefully it is after any fractal
antenna lecturers who have their own prescription working through
their system. [These guys are long on wind and short on results.]

Hi Hank,

Any sense of efficiency is as you already guessed: in the
manufacturing. Rods are very useful if you design within their
limitations (they do not have a closed field). Such a limitation is
marginal if you have excess rod length, but then that goes back to the
bottom line, unless, of course, it costs more to wind a toroid than a
rod. You might want to give the designer the benefit of the doubt and
simply accept that it (toroid or rod) serves the purpose it was put
to.

With a ferrite rod, you have a large air gap in the magnetic path (from one end of the rod to the other). This greatly reduces the effective permeability, so you get less impedance for a given number of turns. But it also reduces the flux density. In baluns, high flux density can cause core heating, which can be a problem at high power levels, but at least for high permeability ferrites, core saturation isn't a problem. (The core will get extremely hot at flux levels well below saturation.) But if the winding has DC or low frequency AC on it, saturation can be a problem. I suspect that rods are used for grounded grid linears because of the DC the winding has to carry. The same thing could of course be done with a gapped toroid, EI, pot, or other kind of core, but rods are relatively inexpensive and convenient.

Toroids aren't necessarily more efficient, it's just that you can get more impedance for a given number of turns, all else being equal.

Yes,

Interesting thing- It reverberates between the Van Allen Belt and the
Ionisphere at 10Hz

10Hz is also the freq your Brain's Alpha Waves measure out at.

Sounds like a candidate for failure if you attempt to follow through
on that thought.

>There was a short piece of magnet wire still stuck inside the

>simple Faraday shield.

A piece of wire would be hard pressed to serve that function. Stuck
in the insulator? Descriptive, but not very informing.

>How many turns, and what spacing was it? And, how
>many turns in the main coupling winding around the toroid (L81)? I count 64
>remaining on this one, which may be close to the original number.

Well, at least that offers some place to start. It also suggests a
good amount of isolation, but simultaneously brings the prospects of
becoming tuned at an inappropriate frequency through stray
capacitance, perhaps this is justifies your assumption of there being
a faraday shield.

>
>Second, some component values. The trimmers (C80 & 87) connected to the
>center conductor were probably in the range of 7 pf. Is that correct?

Seems reasonable, but I doubt both are the same value as they form a
divider that will offer roughly the same ratio as the two resistors or

other coupling ratio this circuit uses.

>
>Are the RF chokes (incorrectly shown as C82 & 84) 0.5 or 1 mH, or something
>else?

Again, this and the 0.01 caps serve to filter the products of both
rectified outputs in the design.

>All constructive comments appreciated, and yes, Reg, I know measuring SWR
>doesn't tell you much. I just want it for a relative output indicator.

Hi George,

Seems like the handbook would offer enough clues (I can't see either
your schematic nor the one you cite from the handbook). There must be
about a dozen passive components here: one transformer with three
(some are two) connections, two caps coupling from it, two resistors
terminating the secondary, two diodes, two diode loads (probably
variable to calibrate forward and reverse scales and perhaps more
resistors simply to limit range of adjustment), two chokes and two
caps to filter the metering current derived from the loads. There are
variations to this design that all go towards the same goal and their
size and connections vary accordingly, but generally show a symmetry.

The only mystery that remains is the winding ratio, 1:64, and the
shielding. The ratio seems OK. If you add a shield, it can only be
terminated at one end, otherwise you short out the induced signal (and
would probably blow the wire like a fuse). Skip the shield and test
the ratio by building the Handbook circuit. If the forward to back is
out of whack, the turns ratio is off, or the capacitive divider is.
Choose one and vary it (the ratio of the caps or the turns). Examine
the two caps or their values in the schematics and determine what
range of ratios they would support.

Since my degree is in power engineering, I guess I have to butt in.
The AC power factor is the ratio of watts to volt-amps and it could
indeed be applied to the *total* power in a transmission line with
reflections. It's not very useful in a transmission line because that
watt/volt-amp ratio varies depending on where one is on the SWR circle.

V and I have to get out of phase in a transmission line with
reflections. That's the way we achieve impedance transformation
using a transmission line and why many people need an antenna
tuner.

There is no current because the forward current wave and the
reflected current wave interfere with each other, i.e. they are
180 degrees out of phase and of equal magnitude.

> Being that the watt meter reads voltage from both directions at once
> (can't distinguish voltage

When the total current goes to zero at an open-circuit, the voltage
phasors add. The sampled voltages add to the sampled currents to
give the wattmeter reading.

Don't bother, Roy. The SWR circle on a Smith Chart will give you exactly
the phase angle between the total voltage and the total current. The
phase angle of the impedance point is the same as the phase angle between
the total voltage and total current.

Hi Cecil,

This is not an answer for specifics on your "Particular kind" of
interference and nor does it explain what makes it different from what
you percieve to be other kinds.

> waves that emerge ... identical to the way they were before
> waves that don't emerge at all
>Hint: One set of waves doesn't get canceled and one set does.
makes no sense at all. The statement violates the conservation of
energy (where did the canceled energy go?). You have less energy at
the end than you do at the begining and you haven't explained where
the balance is.

Show me the balance and how it correlates to this "Particular kind" of
interference.

Hi David,
From what I have read, if you get struck by lightning, then nothing can save you (or your gear).
As regards mains safety, why don't we then have an independent earth for fridges/tv's etc?
I'm not trying to be awkward, just asking the questions!
Thanks.

CAM wrote:
"One set of waves doesn`t get cancelled and one set does."

In the composition and resolution of vectors, if memory serves, two or more voltages or currents of the same frequency (and traveling in the same direction on a common path) must add to produce a composite of the same frequency. Upon this composition, the constituents are indistinguishable.

So, energy emerging from a transmitter and re-reflected energy have their individual voltages in-phase with their currents. The voltages of the same frequency must merge as vectors and the currents also must merge.

Post merger, we have one voltage and one current in one direction away from the transmitter. The wave traveling toward the transmitter is incmpatible, due to its 180-degree phase opposition, with the forward wave.

Best regards, Richard Harrison, KB5WZI

A safety ground (earth connection) is needed if Andy`s QTH is grounded, or earthing is practical, as David Robbins wrote. The dipole Andy uses may become unbalanced with respect to its feedline and introduce r-f to the shack. A rig ground may mitigate the effects.

Best regards, Richard Harrison, KB5WZI

> you percieve to be other kinds.

I can't say it any plainer, Richard. Perhaps my vocabulary is
failing me. There exists interference where the two waves flow
through each other unmolested. This happens when there is
no change in characteristic impedance of the medium, e.g. forward
and reflected waves meeting in a 50 ohm transmission line. There
exists interference where the two waves undergo destructive
interference such that their separate identies are lost.

> makes no sense at all. The statement violates the conservation of
> energy (where did the canceled energy go?).

In a transmission line, the energy reverses direction, i.e. it is
reflected. Waves can be canceled but the energy in the wave cannot
be canceled even though Dr. Best says it can.

> Show me the balance and how it correlates to this "Particular kind" of
> interference.

Discuss the simple example at http://www.qsl.net/w5dxp/fig2.gif and
all will become clear to you.

I used one in college and it worked well. The radiation pattern
is not broadside symmetrical and the feedline radiates.

4648. Daiwa or Alpha Antenna Switch: Opinions On ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-12-13 13:54:18 UTC
From: Robert11 <rgsrose@tiac.net>
Message-ID: <atcp10$2dj$1@slb5.atl.mindspring.net>
Source record: 129185

Hello:

Have decided to purchase either a Daiwa or an Alpha antenna switch.

Do listening only.

Will need two; one (the cheaper version) for below 30 MHz, and one for the above 30 MHz with N connectors.

Have looked thru many posts on antenna switches on the newsgroups, etc., and can find pretty much an even split between those that think Daiwa are poorly made, inferior construction, etc.,
and those that think the same for the Alpha brand ("nothing but a cheap wafer switch," etc.).

A bit surprising; imagined that there would be a concensus, but apparently not.

Since it looks like it will have to be either one of these two, was wondering if anyone would care to add their thoughts?

thanks

> indistinguishable.

That's true if the waves are coherent and traveling in the same direction. But such phasor addition can result in two waves traveling in opposite directions in a transmission line, i.e. the superposition of two waves can result in reflections. Dr. Best doesn't seem to realize this.

> So, energy emerging from a transmitter and re-reflected energy have
> their individual voltages in-phase with their currents. The voltages of
> the same frequency must merge as vectors and the currents also must
> merge.

That's assuming re-reflection happens. Re-reflection can only happen at an impedance discontinuity. In a signal generator with an isolator and isolator load equal to Z0, there is no re-reflection. I don't think we can say that all ham transmitters re-reflect 100% of the reflected power except by definition of the word "delivered".

> Post merger, we have one voltage and one current in one direction away
> from the transmitter. The wave traveling toward the transmitter is
> incompatible, due to its 180-degree phase opposition, with the forward
> wave.

The wave traveling toward the transmitter is not incompatible with the forward wave all up and down the transmission line so why is it necessarily incompatible with the transmitter? If the reflected wave does not see an impedance discontinuity at the transmitter, it will not be re-reflected. So the question is: Does reflected energy *always* see an impedance discontinuity at *every* transmitter and if so, does the impedance discontinuity cause a Zg match point that re-reflects all the reflected power and doesn't allow any reflected energy to flow through the generator?

Thousands of radio/TV stations and commercial base stations
get hit by lightning each year without damage. A proper ground system
is required, as well as protective equipment which diverts the surge
around the equipment, not through it.

> As regards mains safety, why don't we then have an independent earth for

I thought fridges now used three wire plugs? They should be required to.
Manufacturers are cheap and meet minimal requirements.

Andy Cap wrote:
"---why don`t we have an independent earth for fridges / tvs etc?"

Fridges aren`t attached to lightning rods in the sky (antennas). Fridges don`t radiate r-f.

Outdoor TV antennas require safety earthings to detour lightning induced energy around people and contents of connected spaces. The earth connection is also needed to reduce shock risk from contact with an antenna or mast.

Best regards, Richard Harrison, KB5WZI

>> yes, if not for rf then at least for lightning and ac mains safety.

Andy is in Britain, where national wiring regulations for homes are not so stringent about lightning, because we have much less of it than in most parts of the USA. (Our regulations find other things to be paranoid about instead.)

There are three different reasons for grounding in an amateur station: protection against routine mains faults (broken wires or shorts), protection against lightning (including various sizes of induced surges, which are much more common than direct strikes), and to help make the antenna work.

Not all antennas require a ground connection in order to make them work (eg a dipole doesn't) but they are all lightning attractors so they may need a protective ground. If so, it should be as close as possible to the antenna.

The reason why domestic appliances often don't have a ground wire is that they aren't stuck up in the air outdoors. But such appliances are *always* double-insulated instead. TVs are an exception: they are often connected to outside lightning attractors, but they are double-insulated from the mains.

The RF/lightning ground and the mains ground (earth) meet in your shack, so it's a good idea to keep your RF out of the mains wiring by means of a large RF choke. Likewise the choke helps to keep mains-borne noise out of the radio gear. All your mains outlets to the shack should come through a single feed for safety shutdown reasons, and that's also where the RF choke should go.

As others have noted recently, a scrapped TV deflection yoke makes a good ferrite core (you'd pay a fortune for a toroid that size). About 10-15 turns of *all three* mains wires wound through the neck will be effective for HF. Since the mains earth conductor is continuous through

the choke, it doesn't affect mains safety.

That solution might not be valid in the USA, but in Britain the main protection against lightning is home insurance, and/or the special amateur radio policy that RSGB has negotiated.

I heard those switches are expensive because they are made for trasmitting
and handling the power.
I think it would be the best if you make your own switch if you intend to
use it for listening only, which is very easy.

SWR is a manifestation of the above.

CAM also wrote:
"This happens when there is no change in characteristic impedance of the medium--."

A discontinuity (impedance bump) is needed to generate reflections. VSWR is a manifestation of impedance resulting from wave inteference.
Every maximum and minimum is not a discontinuity.

Equal and opposite waves, as Cecil says, don`t go away. Energy annihilation is not allowed. Only the effect of counterbalanced waves at a point, nulls out.

Andy is in the UK and their electrical system is quite different from North American standards (not just voltage and frequency, but also in some fundamental philosophies as well, like grounding and loop circuits fed from two ends).

For the benefit of Andy, in Canada (probably the same in the US), the rule is that appliances must be either 'double insulated' or grounded. Fridges here are usually grounded - not for lightning nor RF, but in case of a short circuit from hot to chassis, the fuse will blow instead of killing someone. TVs are usually in the double insulated camp and usually have only a two-prong plug.

Henry Kolesnik wrote:
"---explain SWR on less than 1/2 wave length line."

Easy. The variations seen as SWR exist in any length of line to an extent which depends on the reflection from a mismatch. It`s the extent we are interested in. We want to know the reflected and forward powers or the reflection coefficient.

All you need to know to determine the SWR which would exist in any length of ideal transmission line are the forward and reflected powers or the reflection coefficient. Seldom is a determination of maximum and minimum voltages made to determine SWR. We use a power meter or a bridge which indirectly (as nearly all electrical measurements are indirect) indicates SWR. The SWR meter is scaled to read SWR. The power meter is scaled to indicate power and its readings can be inserted in a formula which accurately indicates the SWR which would exist on that ideal line of any length.

Best regards, Richard Harrison, KB5WZI

Henry Kolesnik wrote:
"Can V and I get out of phase on a line---?"

A line with reflections has voltage and current maximums which are shifted by 90 degrees with respect to each other. This is only SWR. It is the sum of the forward and reflected waves on the line.

In a lossless line, the individual forward and reflected waves have in-phase and out-of-phase Vand I relationships enforced by the construction of the line.

I know it is so because of countless measurements which prove it.

Best regards, Richard Harrison, KB5WZI

Hi there. I currently have a tv antenna tower with a rotor and the best Radio Shack antenna I could buy 4 years ago. It's performance has been good but there is one station, channel 3 that is located a little over 100 miles away I would like to get. At certain times of the day it comes in a little but is not watchable. (Can just make out the lines of a person throuh the snow). I was toying with the idea of putting another antenna tuned to this channel on the top of the mast my main antenna is on. I am new to constructing antennas and all this but is this feasible? Coould I weld something together out of emt conduit? Where could I get the specifics on the size it needs to be? How would I hook the antennas together correctly without getting "ghosts" or other undesireable affects?

Any help would be appreciated!

Thanks Ian (and also others who contributed)- very helpful.
I've got your book (which is a real mine of information), read your column,
and I'll have a look at your website too!

If you don't already have one, a preamplifier mounted at the antenna is highly recommended.

The usual single-channel antenna would be a Yagi but at channel 3 it will be a little bit difficult to get decent bandwidth. The reason is that channel is 60-66 MHz and this is pretty wide percentage wise for a Yagi.

The best alternative may be a log periodic dipole (LPD). To get a lot of gain out of these it will have to be pretty long. I suspicion however, that you probably don't need too much gain over what your existing antenna has. This is because I doubt that your antenna has much gain at CH 3.

(See: http://www.conformity.com/0005emc.html for a description of the LPD.) There are also a couple of programs floating around the net for designing these.

You most certainly can add another antenna but you need to use an appropriate transmission line coupler to do so. If both antennas are not pointed in the same direction, you will have the possibility of ghosting.

EMT though is definitely not recommended. You should use aluminum.

Wes

Hi Cecil,

This has run on too long without an answer except for the perennial
unveiling of the steamroller.

Blame it on poor language if you will, but even that defense fails to
strip away the unnecessary complexity that attends your discussion.
Occam's Razor insists that the simpler understanding we have of
interference does not require this additional baggage. As this added
complexity appears to be necessary for your logic, I see no purpose in
pursuing baroque theories that only you seem to be able to understand.

Name one other correspondent here on this board (or better yet, let
them identify themself) that can serve as a surrogate to your
discussion and let me see if I can get an answer to
>If I see the projection of the sun through a double slit against a
>screen, I will see light and dark bars due to "interference." There
>is absolutely nothing here that requires an impedance discontinuity.
>There is no causal effect enforced on either of the two slits, one on
>the other (they remain independent sources). The two waves are wholly
>independent of each other before they fall on the screen, and after
